Macro-Drip (20gtt/ml) or Micro-Drip is set of choice for this infusion						
Titrate to minimum effective dose. Allow 3-5 minutes between dosing changes to sedative and hemodynamic effects.						

ROCURONIUM

♀C, **Lactation?**(Caution)

Trade Name: **Zemuron**

Class / Mechanism of Action

Nondepolarizing Neuromuscular Blocking Agent (Paralytic)
Blocks acetylcholine from binding to motor neuron receptors inhibiting depolarization.
Onset of action IV: 1-2 minutes, Duration: approximately 25-40 minutes (increases with higher doses)

Indications

Labeled Indications: Rapid Sequence Intubation/Paralysis and routine endotracheal intubation, facilitates mechanical ventilation in ICU patients

Contraindications

- Hypersensitivity (eg, anaphylaxis) to rocuronium, other neuromuscular-blocking agents, or any component of the formulation

Adverse Reactions / Precautions

- Resistance may occur in burn patients (>30% of body) for period of 5-70 days after injury
- High potential for interactions: Numerous drugs either antagonize (eg, acetylcholinesterase inhibitors) or potentiate (eg, calcium channel blockers, certain antimicrobials, inhalation anesthetics, lithium, magnesium salts, procainamide, and quinidine) the effects of neuromuscular blockade; use with caution in patients receiving these agents.
- **Provides NO analgesia or sedation!**
    - **Must provide appropriate sedation and analgesia prior to paralytic use and throughout maintenance.**

Dose and Administration:

ADULT

RSI:
IV Push:

- **1mg/kg**
  (Dosing ranges from **0.6-1.2 mg/kg**)

Note: In adult patients with morbid obesity (BMI >40 kg/m2), use dose of 1.2 mg/kg using ideal body weight (IBW)

Maintenance dosing: (unlabeled and unreferenced dose)
IV Push:

- **1 mg/kg IV/IO q30-45min** PRN or 8-12 mcg/kg/min IV/IO
  (Dosing ranges from **0.6-1.2 mg/kg**)

PEDIATRIC Always Reference BROSELOW Tape

RSI:
IV:

- **1mg/kg**
  (Dosing ranges from **0.6 - 1.2 mg/kg**.)

Maintenance bolus dosing: (unlabeled and unreferenced dose)
IV Push:

- **1 mg/kg every 30-45 minutes**

(Dosing ranges from **0.6 - 1.2 mg/kg**.)

SODIUM BICARBONATE ♀C, Lactation Yes

Class / Mechanism of Action

Alkalinizing Agent; Antacid
Provides bicarbonate ion to neutralize hydrogen ion concentration and raise blood and urinary pH
Onset of action IV: 15 minutes, Duration 1-2 hours

Indications

Labeled Indications: Management of metabolic acidosis, hyperkalemia, overdose of certain drugs (including tricyclic antidepressants and aspirin), and gastric hyperacidity.

Contraindications

- Alkalosis, hypernatremia, hypocalcemia
- severe pulmonary edema
- Unknown abdominal pain

Adverse Reactions / Precautions

- Use should be reserved for documented metabolic acidosis and for hyperkalemia induced cardiac arrest. Routine use in cardiac arrest is not recommended.
- Avoid extravasation, tissue necrosis can occur.
- Can cause Hypernatremia, hypocalcemia, hypokalemia, intracranial acidosis, metabolic alkalosis

Dose and Administration: ADULT	PEDIATRIC Always Reference BROSELOW Tape
TriCyclic Antidepressant OD IV: • **1mEq/kg**; May repeat to maintain QRS <100 • Start Maintenance Infusion: **100-150mEq** (2-3 amps) in 1 L D5 / NS @ 100-200 mL/hr IV **Cardiac arrest (ACLS Guidelines, 2015):** IV: • **1 mEq/kg/dose**; repeat doses should be guided by arterial blood gases **Note:** Routine use in cardiac arrest is not recommended. Use may be considered in cases of prolonged cardiac arrest once adequate alveolar ventilation and effective cardiac compressions have been established. In some cardiac arrest situations (eg, metabolic acidosis, hyperkalemia, or tricyclic antidepressant overdose), sodium bicarbonate may be beneficial. **Hyperkalemia (ACLS Guidelines, 2015)** IV: • **50 mEq** over 5 minutes **Metabolic acidosis:** If acid-base status is not available: **2-5 mEq/kg** infusion over 4-8 hours	• **Follow Adult Dosing**

SUCCINYLCHOLINE

♀C, **Lactation?**(Caution)

Trade Name: **Anectine**

Class / Mechanism of Action

Depolarizing Neuromuscular Blocking Agent (Paralytic)

Acts like acetylcholine, produces myoneural depolarization causing sustained flaccid skeletal muscle paralysis. Onset of action IV: 30-60 seconds, Duration 5-9 minutes with single dose

Indications

Labeled Indications: Rapid Sequence Intubation and routine endotracheal intubation

Contraindications

- Hypersensitivity to succinylcholine or any component of the formulation
- Acute phase of injury following major burns, multiple trauma (greater than 5 days after injury)
- Myopathies associated with elevated serum creatine phosphokinase and myasthenia gravis
- **DO NOT USE IN PATIENTS WITH BURNS, CRUSH INJURIES, OR HYPERKALEMIA**
- Re-Dosing is not advised due to increased risk of Hyperkalemia
- Neuromuscular disease (Muscular dystrophy, Spinal Muscular Atrophy, etc.)

Adverse Reactions / Precautions

- May cause Bradycardia, Malignant hyperthermia, and increased intraocular pressure
- Severe hyperkalemia can develop in cases of chronic abdominal infection, burn injury, children with skeletal muscle myopathy, subarachnoid hemorrhage, or conditions which cause degeneration of the nervous system commonly greater than 5 days old. Potassium increase of 0.5 mEq/L is expected with use.
- **Provides NO analgesia or sedation!**
    - **Must provide appropriate sedation and analgesia prior to paralytic use and throughout maintenance.**

Dose and Administration:

ADULT

RSI/ Neuromuscular blockade:

IV:

- **1-1.5 mg/kg**

Note: Pretreatment with 10% dosage of non-depolarizing agents prior to neuromuscular-blockade with Succinylcholine is **NO LONGER ADVISED**

PEDIATRIC Always Reference BROSELOW Tape

RSII / Neuromuscular blockade:

IV:

- <10kg:
    - Initial: **1.5-2 mg/kg/dose**
- >10kg:
    - Initial: **1-1.5 mg/kg/dose**

Note: Pretreatment with 10% dosage of non-depolarizing agents prior to neuromuscular-blockade with Succinylcholine is **NO LONGER ADVISED**

THIAMINE	♀A, **LactationYes**(Caution)	Trade Name: **Vitamin B1**

Class / Mechanism of Action

Vitamin, water soluable
Essential coenzyme in carbohydrate metabolism. Onset of action IV/IM: Rapid

Indications

Labeled Indications: Treatment of thiamine deficiency including beriberi, Wernicke's encephalopathy, Korsakoff's syndrome, neuritis associated with pregnancy, or in alcoholic patients

Contraindications

- Hypersensitivity to thiamine or any component of the formulation

Adverse Reactions / Precautions

- Administration of dextrose may worsen acute symptoms of thiamine deficiency; use caution when low thiamine is suspect

Dose and Administration:	**ADULT**	**PEDIATRIC** Always Reference BROSELOW Tape
	<u>AMS; Seizure; Syncope; Malnutrition; Vomiting and Diarrhea; w/ Hx of ETOH abuse:</u> IM/IV: • **100mg/day**	**<u>AMS or Seizure w/ signs of Malnutrition:</u>** IM/IV: • **25mg/day**

TRANEXAMIC ACID

♀B, **Lactation: Yes**(Caution) Trade Name: **Cyklokapron/Lysteda**

Class / Mechanism of Action

Antifibrinolytic Agent, Hemostatic Agent

Displaces plasminogen from fibrin resulting in inhibition of fibrinolysis and inhibits the proteolytic activity of plasmin

Indications:

- Trauma-associated hemorrhage: Casualty likely needing blood transfusion (hemorrhagic shock, elevated lactate, one or more major amputations, penetrating torso trauma, or evidence of severe bleeding)
- Post-Operative Hemorrhage by dissection, enteric staples or suspected internal bleeding
- Signs or symptoms of significant TBI or altered mental status associated with blast or blunt trauma
- Postpartum Hemorrhage (continued bleeding despite Oxytocin and fundal massage)

Contraindications

- **TXA is contraindicated in trauma if dose is not given within first 3 hours following Traumatic event (Ideal dosing time-frame is within 1 hour of trauma)**
- Hypersensitivity to tranexamic
- Subarachnoid hemorrhage
- Thromboembolic disease (Cerebral Thrombosis, DVT, PE)

Adverse Reactions / Precautions

- Disseminated intravascular coagulation (DIC): Use with extreme caution in patients with DIC requiring antifibrinolytic therapy; patients should be under strict supervision of a physician experienced in treating this disorder. TXA should be used in Pt.'s with trauma related DIC however.
- Thrombosis (especially when given after 3hr from injury**)**
- Seizure

Dose and Administration:

ADULT

Trauma-associated hemorrhage (unlabeled use):

IV:

- Initial Dose: **2 gram of TXA** in 100 cc NS or LR ASAP via IV/IO Bolus, or 2 gram IV/IO push (1 gram over 1 minute per push) but **NOT** later than 3 hours after injury.
- If patient received **1 gram of TXA** prior and <3hrs from time of injury: **1 gram TXA** IV/IO push over 1 minute or mixed in 100cc NS or LR Bolus. If >3hr from time of injury: ***DO NOT*** administer TXA.

Suspected Post-Operative Hemorrhage by dissection, enteric staples or suspected internal bleeding:

- Initial Dose: **2 gram of TXA** in 100 cc NS or LR ASAP via IV/IO Bolus or 2 gram IV/IO push (1 gram over 1 minute push) but **NOT** later than 3 hours after start of suspected hemorrhage.

PEDIATRIC Always Reference BROSELOW Tape

Trauma-associated hemorrhage (unlabeled use):

IV:

- Initial Dose: **15mg/kg** via IV/IO Bolus (goal within 1 minute),

VASOPRESSIN

♀C, **Lactation?**(Caution)

Trade Name: **Vasostrict**

Class / Mechanism of Action

Antidiuretic Hormone Analog-Vasopressor

Vasopressin, at therapeutic doses used for vasodilatory shock, stimulates the AVPR1a (or V1) receptor and increases systemic vascular resistance and mean arterial blood pressure; in response to these effects, a decrease in heart rate and cardiac output may be seen.

Onset of action IV: Rapid with peak effect occurring within 15 minutes of initiation of continuous IV infusion. Duration: Within 20 minutes after IV infusion terminated.

Indications

Labeled Indications: Treatment of hypotension, vascular failure in shock

Contraindications

- Hypersensitivity to Vasopressin or any component of the formulation
- Use with caution in patients with asthma, cardiovascular disease, renal disease, or a history of seizure disorder

Adverse Reactions / Precautions

- **No applicable use in hemorrhagic shock unless fluid replacement therapy maximized! Maximize use of Blood products / Crystalloids before considering use in hemorrhagic shock.**
- Assure adequate circulatory volume to minimize need for vasoconstrictors. Monitor BP closely, avoid hypertension and adjust infusion rate as needed.
- Vesicant: Avoid extravasation, will cause tissue damage/necrosis, ensure proper needle placement
- Cardiac arrhythmias are possible, monitor with 12 lead EKG

Dose and Administration: **ADULT** **PEDIATRIC** Always Reference BROSELOW Tape

Hypotension / Shock:

Vasopressors should be used if patient is hypotensive after fluid resuscitation to maintain mean arterial pressure (MAP) ≥65 mmHg.

Use in addition to norepinephrine for raising MAP to target or to decrease norepinephrine dosage.

Titrate to lowest effective dose.

IV Infusion:
4 Unit bolus IV/IO followed by **0.04 U/min** infusion to maintain MAP>65 mmHg

Hypotension / Shock:

Limited data available; efficacy results have varied.

IV Infusion:

- **0.17 to 8 MILLIUNITS/kg/minute (0.01 to 0.48 units/kg/hour)**

VECURONIUM

♀C, **Lactation?**(Caution)

Trade Name: **Norcuron**

Class / Mechanism of Action

Nondepolarizing Neuromuscular Blocking Agent (Paralytic)
Blocks acetylcholine from binding to motor neuron receptors inhibiting depolarization.
Onset of action IV: 1.5-3 minutes, Duration: approximately 30-60 minutes

Indications

Labeled Indications: Endotracheal intubation, facilitates mechanical ventilation in ICU patients

Contraindications

- Hypersensitivity to vecuronium or any component of the formulation

Adverse Reactions / Precautions

- Resistance may occur in burn patients (>30% of body) for period of 5-70 days after injury
- High potential for interactions: Numerous drugs either antagonize (eg, acetylcholinesterase inhibitors) or potentiate (eg, calcium channel blockers, certain antimicrobials, inhalation anesthetics, lithium, magnesium salts, procainamide, and quinidine) the effects of neuromuscular blockade; use with caution in patients receiving these agents.
- **Provides NO analgesia or sedation!**
  - **Must provide appropriate sedation and analgesia prior to paralytic use and throughout maintenance.**

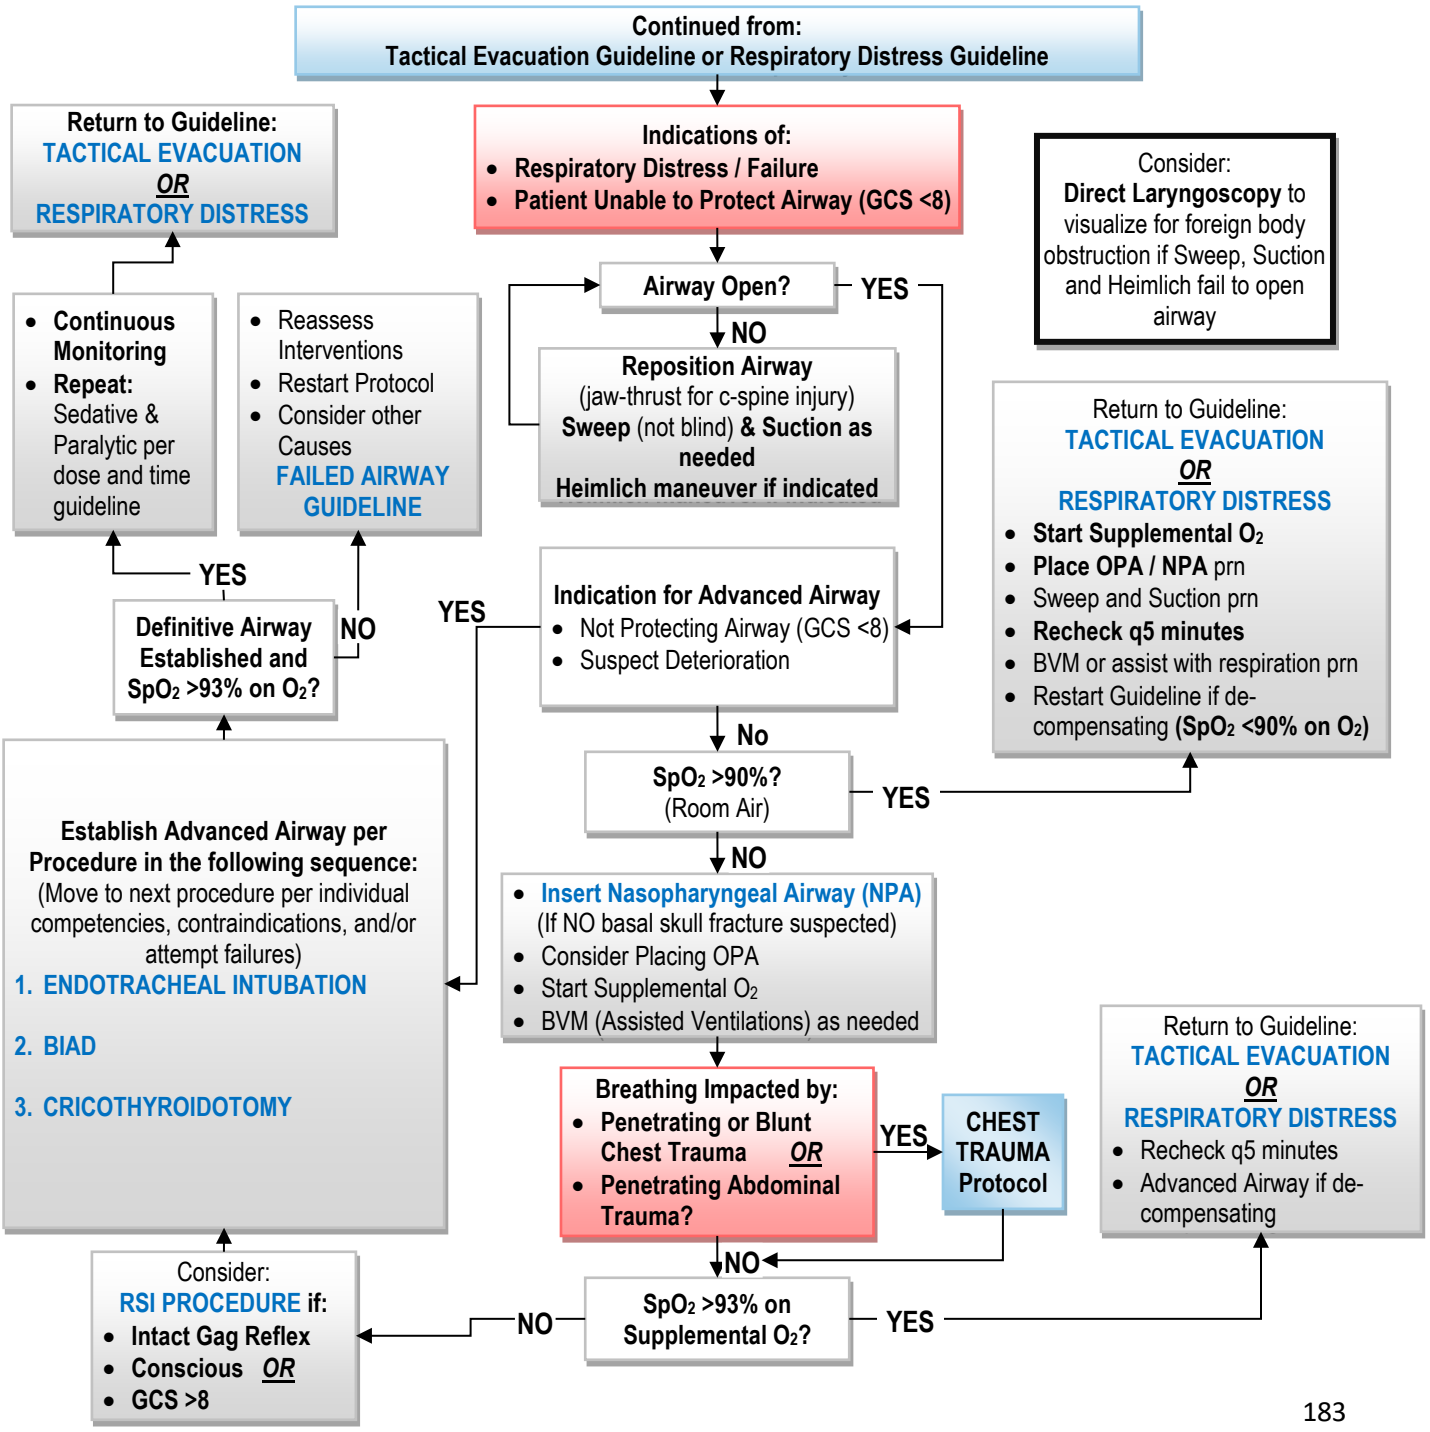
Dose and Administration:

ADULT	PEDIATRIC Always Reference BROSELOW Tape
RSI) and maintenance of paralysis: IV Push: • Induction: **0.1 mg/kg** **Dose range (0.8-0.15 mg/kg)** • Maintenance: **0.1 mg/kg** every 30-60 minutes PRN **Dose range (0.8-0.15 mg/kg)** IV Continuous infusion: • **1 mcg/kg/min** and titrate to 2:4 train of four (TOF) if stimulation devise is available. **Note:** Paralytic use and management: If available, utilize the train of four stimulation device with either the temple or radial/ulnar nerve placement. Maintain paralysis at a level of 2/4 twitches with TOF stimulation. **Note:** Vecuronium is only recommended for use in RSI in the absence of available Succinylcholine or Rocuronium, as they are the preferred induction agents.	**RSI and maintenance of paralysis::** IV Push: • Induction: **0.1-0.15 mg/kg** • Intermittent bolus dosing: **0.1 mg/kg** every 30-60 minutes PRN IV Continuous infusion: • **1-2.5 mcg/kg/minute**

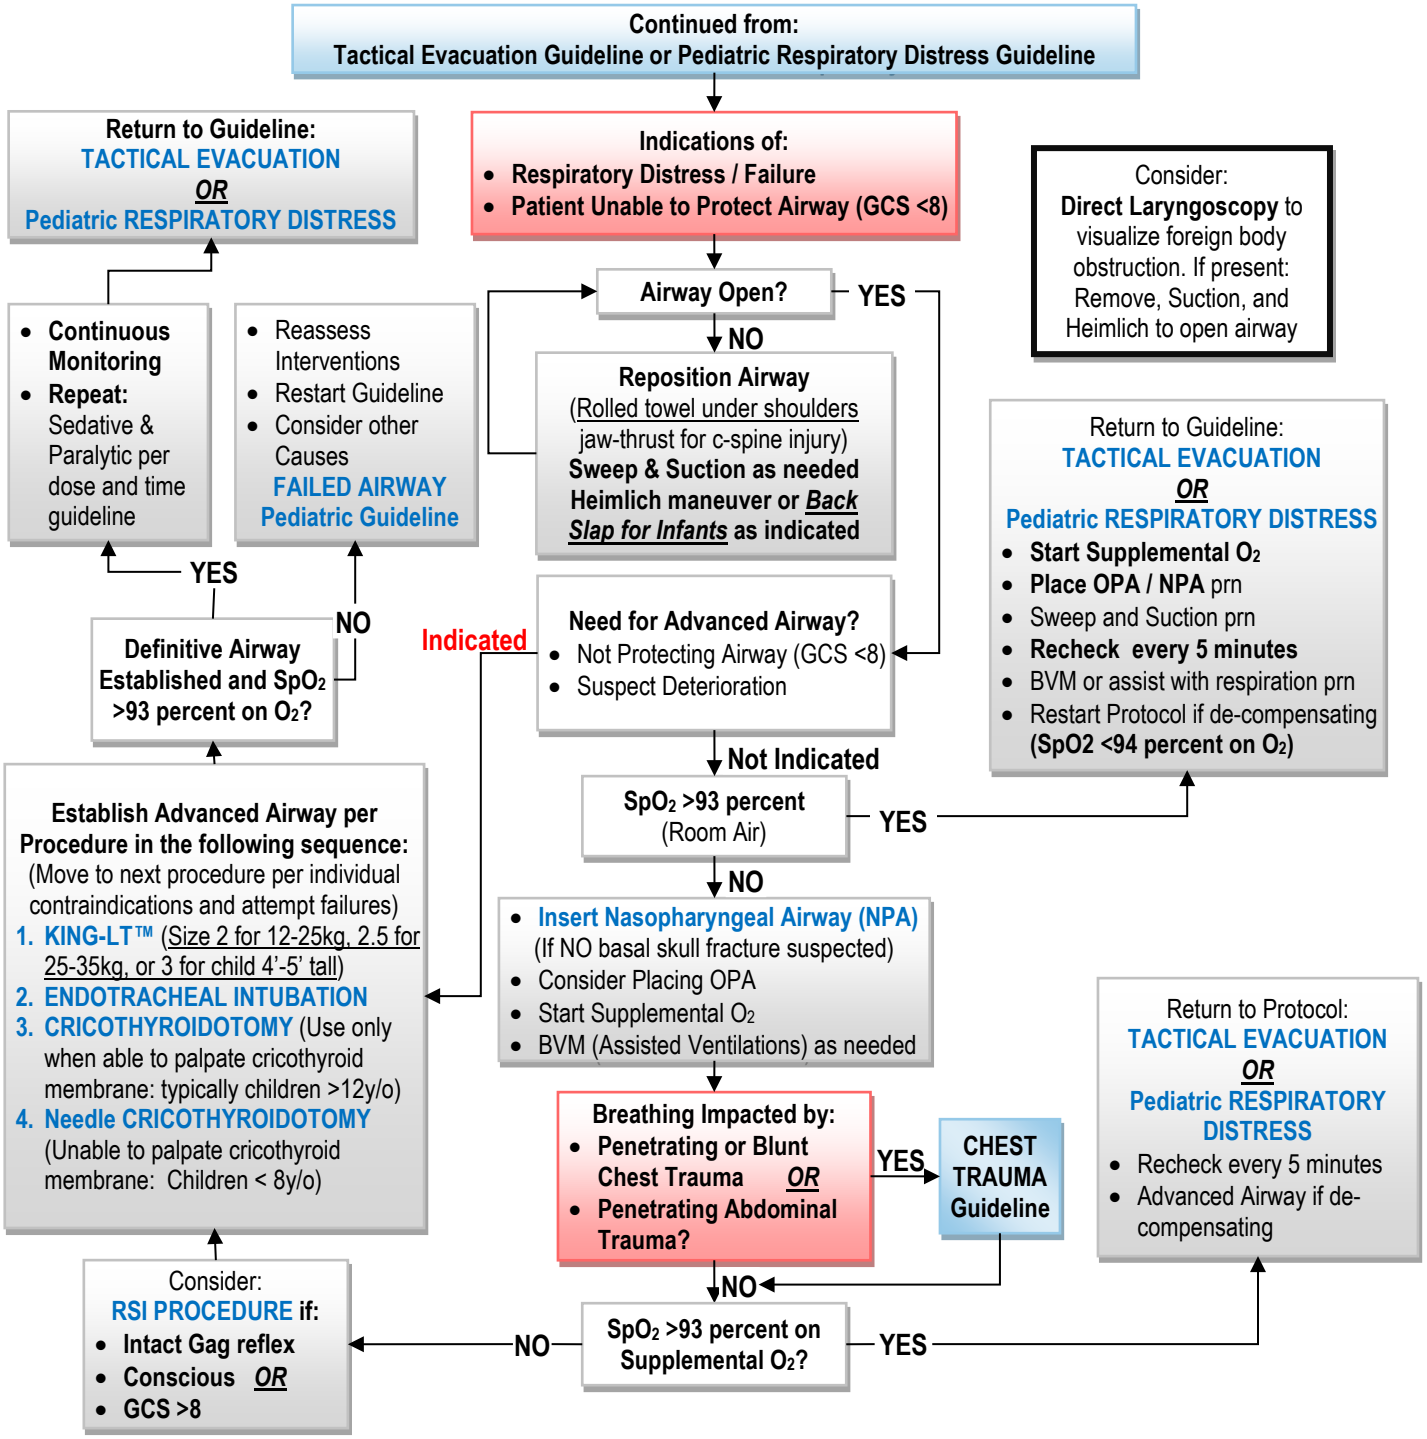
AIRWAY

Signs and Symptoms of Distress and/or Failure:

- **SpO_2 Decreasing or <90%** (Room Air) with / without supporting Signs / Symptoms of:
  - Tachypnea, Tachycardia, Fever, Cough, Wheezing, Rhonchi, Rales, Shock
- **Difficulty Breathing or Excess Work** as demonstrated by:
  - Pursing of Lips, Accessory Muscle Involvement, Cyanosis, Decreased Ability to Speak, Diaphoresis
- **Airway Obstruction** due to Trauma, Edema, Excess Secretions, Foreign Body, or Tongue
- **Apnea**
- **Decreased LOC** (GCS <8)



PEDIATRIC AIRWAY



Continued from:
Tactical Evacuation Guideline or Pediatric Respiratory Distress Guideline
Indications of:
• Respiratory Distress / Failure
• Patient Unable to Protect Airway (GCS <8)
Consider:
Direct Laryngoscopy to visualize foreign body obstruction. If present: Remove, Suction, and Heimlich to open airway
Airway Open?
YES
NO
Reposition Airway
(Rolled towel under shoulders jaw-thrust for c-spine injury)
Sweep & Suction as needed
Heimlich maneuver or Back Slap for Infants as indicated
Return to Guideline:
TACTICAL EVACUATION
OR
Pediatric RESPIRATORY DISTRESS
• Start Supplemental O2
• Place OPA / NPA prn
• Sweep and Suction prn
• Recheck every 5 minutes
• BVM or assist with respiration prn
• Restart Protocol if de-compensating
(SpO2 <94 percent on O2)
Need for Advanced Airway?
• Not Protecting Airway (GCS <8)
• Suspect Deterioration
Indicated
Not Indicated
SpO2 >93 percent
(Room Air)
YES
NO
• Insert Nasopharyngeal Airway (NPA)
(If NO basal skull fracture suspected)
• Consider Placing OPA
• Start Supplemental O2
• BVM (Assisted Ventilations) as needed
Breathing Impacted by:
• Penetrating or Blunt Chest Trauma OR
• Penetrating Abdominal Trauma?
YES
CHEST TRAUMA Guideline
NO
SpO2 >93 percent on Supplemental O2?
NO
YES
Return to Protocol:
TACTICAL EVACUATION
OR
Pediatric RESPIRATORY DISTRESS
• Recheck every 5 minutes
• Advanced Airway if de-compensating
Consider:
RSI PROCEDURE if:
• Intact Gag reflex
• Conscious OR
• GCS >8
Establish Advanced Airway per Procedure in the following sequence:
(Move to next procedure per individual contraindications and attempt failures)
1. KING-LT™ (Size 2 for 12-25kg, 2.5 for 25-35kg, or 3 for child 4'-5' tall)
2. ENDOTRACHEAL INTUBATION
3. CRICOTHYROIDOTOMY (Use only when able to palpate cricothyroid membrane: typically children >12y/o)
4. Needle CRICOTHYROIDOTOMY
(Unable to palpate cricothyroid membrane: Children < 8y/o)
Definitive Airway Established and SpO2 >93 percent on O2?
YES
NO
• Continuous Monitoring
• Repeat:
Sedative & Paralytic per dose and time guideline
• Reassess Interventions
• Restart Guideline
• Consider other Causes
FAILED AIRWAY
Pediatric Guideline
Return to Guideline:
TACTICAL EVACUATION
OR
Pediatric RESPIRATORY DISTRESS

AIRWAY Pearls

Signs and Symptoms of Respiratory Distress and/or Failure

- **SPO_2 decreasing <90%** (Room Air) with / without supporting Signs / Symptoms of:
  - Tachypnea, Tachycardia, Fever, Cough, Wheezing, Rhonchi, Rales, Shock
- **Difficulty Breathing or Excess Work** as demonstrated by:
  - Purpling of Lips, Accessory Muscle Involvement, Cyanosis, Decreased Ability to Speak, Diaphoresis, Tripod Breathing
- **Airway Obstruction** Due to Trauma, Edema, Excess Secretions, Foreign Body, or Tongue
- **Apnea**
- **Cyanosis,** Central and/or Peripheral: Blue/Pale Tinting and Mottling of Skin
- **Decreased LOC** (GCS <8), **Altered Responsiveness, Weak Cry**

Pearls:

- **PCO_2 is affected by respiratory rate and tidal volume (ventilation), while PO_2 is affected by PEEP and FiO_2 (oxygenation)**
- Capnography is mandatory for all intubations. Record results. Capnometer (standalone END TIDAL CO_2 detector) is an alternate if monitor capnography not available**. For capnography, normal range is 35-45 mm Hg;** adjust vent as needed.
- All intubated patients should receive nasogastric / orogastric tube (time permitting) and continuous pulse oximetry.
- **Maternal Medication:** Adverse effects can include respiratory insult to newborn.
- Pediatric is defined as anyone <12yo.
- **If RSI is impractical or provider is not credentialed to perform**, but patient requires an advanced airway with / without ventilatory support, consider:
  1. Pharmacologically-Assisted Sedation using KETAMINE followed by supraglottic airway device placement (do not attempt BIAD placement without sedation in semi-conscious patients)
  2. Surgical cricothyroidotomy using approved device. (modified 6.0 ET not ideal)
  3. Medical personnel should not actively seek to determine if gag reflex is present by touching the palate, posterior lounge, or posterior pharynx.

RSI MEDICATIONS: IV/IO Doses

Pretreatment:
Fentanyl 3mcg/kg IV
Atropine 0.02mg/kg IV Min: 0.1mg (**Infants <1yo)**

Induction Agents:	**80kg adult dose:**
Etomidate 0.3mg/kg	24mg
*Ketamine 1-2mg/kg	80-160mg
Midazolam 0.1mg/kg	8mg
Propofol 1-2.5 mg/kg	80-200mg

Paralytics:
Vecuronium 0.08-0.15 mg/kg
*Rocuronium 0.6-1.2 mg/kg, q25-40min
Succinylcholine 1.0-1.5mg/kg

Continued Sedation:
Fentanyl 0.5-2mcg/kg, q20-60min
Ketamine 0.5-2mg/kg, q10-20min
Ketamine 0.5-2mg/kg bolus then 0.5-1mg/kg/hr
Midazolam 0.05mg/kg-NO Painl, q15-30m
Midazolam 0.05 mg/kg bolus IV x1 prn, then titrate 0.05-0.1mg/kg/hr IV gtt
Propofol 10-75 mcg/kg/min IV

VOCAL CORD VISUALIZATION MANEUVERS:

- **Ensure correct alignment-** External auditory meatus is aligned with sternal notch and head is in neutral to sniffing position.
- **BURP** = **B**ackward; **U**pward; **R**ightward; **P**ressure on thyroid cartilage.

RSI (Abbreviated: see RSI PROCEDURE as needed)

1. **Preoxygenate** (100% FiO_2 via mask or PPV as needed)
2. **Pretreat** (Premedicate) as able or mission allows (Atropine blocks reflex bradycardia in pediatric (<2y/o only) population)
3. **Induce** (Primary Sedation / Anesthesia)
4. **Paralyze** (Neuromuscular blocking agent)
5. **Wait for Fasciculation, Jaw Relaxation, Absence of Movement**
6. **Pass ET Tube or insert BIAD** (throughout attempt, ensure good O_2 saturation. If below 94% stop and provide PPV)
7. **Confirm Placement and Secure Tube**
8. **Continue Sedation and Paralytic** as needed per dosing time.

Note: Midazolam and Propofol should only be used for continued sedation when pain management is NOT a concern (i.e., Non Trauma Patient or Patient is already on adequate narcotic pain control).

Rescue Breathing Ventilation Rate Without Advanced Airway:

- **NEWBORN** = 40-60/min when performed without compressions
- **Infant / Child** = 1 breath / 3-5 seconds
- **Adult** = 1 breath / 5-6 seconds

VENTILATOR SETTINGS:

- Mode: AC, SIMV, or ASV
- Rate: 14 initially, then adjust PRN
- Tidal Volume: 6mL/kg initially, then adjust 4-8 mL/kg
- I:E = 1:2
- PEEP: 5
- FiO_2: 100% initially. Try to decrease FiO_2 as much as possible while keeping O_2 saturation > 93%.
- **Goal FiO_2 = 50-60% to conserve battery life and O_2, while maintaining patient SpO_2 >93%.**

AIRWAY CONFIRMATION

CLINICAL INDICATIONS:

- Post endotracheal intubation to confirm proper placement of endotracheal tube (ETT)

CONTRAINDICATIONS:

- None

PROCEDURE:

- Primary / First confirmation of proper placement is always good visualization of tube passing through cords.
- Provider or second individual should listen for bilateral breath sounds and absence of gastric sounds. Also evaluate for equal chest rise. Look for ETT fogging.
- Ensure ETT is at appropriate depth and good pilot cuff tension is present.
- **WAVEFORM CAPNOGRAPHY** is gold standard for patient airway monitoring.
- Capnometer: Place onto ETT and bag patient 2-3 breaths. Proper placement will result in color change to Gold / Yellow. Esophageal placement will result in a purple color. (**Gold = good**, **Barney = bad**) Change will only occur with perfusion (e.g. High quality CPR required.)
- Esophageal detection device: Squeeze bulb expressing all air out of the EDD. Place this onto end of ETT. Rapid refilling suggests proper placement (the rigid trachea does not collapse and therefore there is no obstruction to air return). Poor filling or no filling suggests improper placement (the flaccid esophagus will collapse around ETT preventing refilling).
- Pulse oxygenation: After a short delay (30-60 seconds in young children, particularly those with poor perfusion), the pulse oxygenation should increase to normal range (this is not reliable in excessively cold patients, methemoglobinemia, or CO poisoning). Do not extubate if other confirmation measures say it is in!

Document procedure, results, and vital signs.

At any time, doubt as to correct placement should prompt removal of tube, oxygenate with BVM, and re-attempt with BIAD before rescue airway!

BLIND INSERTION AIRWAY DEVICE (BIAD)

CLINICAL INDICATIONS:

Patient with inadequate respiratory drive or respiratory failure due to any reason (e.g., altered mental status, trauma, infection) other than airway burns, anaphylaxis, or other causes of airway swelling / obstruction.

CONTRAINDICATIONS:

- Massive upper airway trauma distorting anatomy
- Penetrating neck trauma

PROCEDURE:

Consider paralytic/analgesia/sedation medications when placing supraglotic airways devices. In any instance of BIAD placement, caregiver must be prepared for vomiting and aspiration.

- Prepare, position, and pre-oxygenate the patient with 100% O_2. Ensure patient on monitor if possible.
- Select appropriate size BIAD and ensure proper cuff inflation / deflation.
- Lubricate with water-soluble jelly.
- Advance tube towards posterior pharynx until seated in correct position.
- Inflate balloon as per package insert and attempt to ventilate with BVM.
- If good airflow / chest rise / PO_2, secure device in place and ventilate patient with BVM / Vent.
- If unable to ventilate / resistance, leave first BIAD in place, deflate balloon, and pass a second BIAD in the same manner as the first (second should only be able to enter the trachea as the first may have entered into the esophagus approx 5-10%). Once second BAID is in place, remove first and inflate the cuff on the second device. Attempt to bag as above. If successful, ventilate patient.

WARNING: BIADs may not prevent or block aspiration of gastric contents.

Document procedure, results, and vital signs.

FAILED AIRWAY

Criteria:

- **Unable to open airway**
- **Two (2) Failed intubation attempts by the most proficient technician on scene**
  - Assumes at least 1 attempt with Supraglottic Airway (unless contraindicated or appropriate size not available) and 2 attempts with ET Tube

OR

- **Intubation contraindicated due to anatomical abnormalities or major airway trauma**

All Attempts as Appropriate:

- **Reposition Airway (jaw-thrust for c-spine injury)**
- **Sweep & Suction (as needed)**
- **Heimlich Maneuver /Abdominal Thrusts / Back Slaps (as indicated)**

Able to Ventilate with BVM

NO → **(*See Pearls)** Attempt to:
Insert Oral Airway
AND/OR
Nasopharyngeal Airway (NPA)
(if NO basal skull fracture suspected)
→ **Continue BVM**

YES

Continue BVM

If adequate ventilation with BVM, continue BVM. If inadequate, continue with protocol.

CRICOTHYROIDOTOMY open, percutaneous (>10 y/o) or needle

Ventilate Patient (per age respiratory rate)

Repsiratory Rate: (breaths/min) without Advance Airway and *NOT* performing BLS.

Infant	30-60
Toddler	24-40
Preschooler	22-34
School Age	18-30
Adolescent	12-18

Pearls:

- Continuous pulse oximetry should be utilized in all patients with an inadequate respiratory function.
- Continuous $EtCO_2$ monitoring should be attached when available to monitor adequacy of ventilation.
- Contraindication for Oropharyngeal Airway (OPA: Intact gag reflex, conscious or semiconscious, severe facial trauma
- Contraindication for Nasopharyngeal Airway (NPA): Known esophageal disease, recent ingestion of caustic substances, severe facial trauma, possible nasal and adjacent (basilar skull) fracture
- **In the setting of significant facial/neck trauma or distortion of anatomy (i.e. angioedema) laryngoscope and intubation may be difficult or impossible. Based on physical examination of the airway, Cricothyroidotomy may be the initial airway of choice. Consider procedural sedation with Ketamine in awake patients.**
- **Cricothyroidotomy can be performed by all medics once approved by medical director. This should be utilized quickly with sever airway trauma or inability to intubate.**
- **Needle Cricothyroidotomy can be performed by all CCFPs once approved by medical director. This should be utilized quickly with severe airway trauma or inability to intubate.**

NASOPHARYNGEAL AIRWAY

CLINICAL INDICATIONS:

- Depressed mental status with need for airway augmentation to ensure patency / access.

RELATIVE CONTRAINDICATIONS:

- Patient at high-risk of aspiration and/or unable to protect airway
- Massive facial trauma, burns, or suspicion of basilar skull fracture (e.g., CSF otorrhea, Battle's sign, raccoon eyes, mechanism).

PROCEDURE:

- Position patient in the sniffing position.
- Select appropriate sized NP tube and lubricate with water-soluble jelly (can measure tube by placing exterior (lipped) end next to nare and tip should reach to angle of mandible).
- Select most patent nare, orient open angle medially, and pass tube in a posterior **– not superior –** direction. If resistance is met, attempt to corkscrew slightly or remove and attempt in other nare. If unsuccessful, try the next smallest sized tube.
- Pass tube until lip of NP tube rests against nare.
- Bag patient with BVM / mask as needed.

Document procedure, results, and vital signs.

Pre-Intubation Checklist

PRE-INTUBATION CHECKLIST	
INSTRUCTIONS FOR USE The Pre-Intubation Checklist serves as a final reference prior to administering a sedative and paralytic during a Rapid Sequence Intubation. Run the checklist to ensure preparation is complete before embarking on induction and paralysis. Refer to **RAPID SEQUENCE INTUBATION** for how to do an RSI.	
PLAN	☐ **Consider Dangerous Physiology Issue: SBP <100, SpO2 <94%, Metabolic Acidosis** ➢ Appropriately modify or avoid RSI in unstable patient ➢ **SBP < 100** → Consider resuscitation with IVF and vasopressors, Lower the dose of sedative ➢ **Sat < 94%** → Consider use of CPAP or BVM with PEEP valve to increase Mean Airway Pressure during Pre-Oxygenation ➢ **Severe Met. Acidosis** → Consider awake intubation or delayed sequence intubation with severe Metabolic Acidosis ☐ **Difficult Airway Evaluation** (LEMON, HEAVEN Criteria) ➢ Consider alternate airway, cricothyrotomy, or modify plan ☐ **Rapid Sequence Intubation, Delayed Sequence Intubation, Rapid Sequence Airway (SGA), or Cricothyrotomy** ➢ Choose the most appropriate technique for physiology and anatomy ☐ **Evaluate Cricothyrotomy Landmarks and Assess Procedural Difficulty** ☐ **Induction Agent / Paralytic** ➢ Choose and draw up appropriate Sedative and Paralytic ☐ **Push-Dose Pressors** ➢ Consider drawing up or administering Push-dose Epinephrine ☐ **Post-tube Sedation / Analgesia** ➢ Prepare Post-intubation Sedation and Analgesia ☐ **Consider Pretreatment 3-5 minutes prior** ➢ Fentanyl (TBI, CVA, MI, Ao Dissection); Atropine (Pediatric) ☐ **Failed Airway Plan Verbalized to the team** ➢ Discuss management plan for failed intubation
PATIENT PREPARATION	☐ **PreOx** ≥ 3 minutes with 15 LPM NRB or BVM + PEEP, and NC 4-6 LPM ☐ **Apneic Oxygenation with NC 15 LPM** once Induced/Sedated ☐ **Oxygenated ≥ 94%** prior to Induction ➢ Consider using CPAP or BVM + PEEP if unable to reach 94% with NRB ☐ **Positioning**: 30° Head-up for Pre-Ox, Ear-to-Sternal Notch for Intubation ➢ If C-Spine Consideration, open front of C-Collar and perform Manual In-line Stabilization ☐ **Monitor is Visible** (HR, BP, SpO2%, RR, etCO2) ☐ **Reliable IV Access Tested**
EQUIPMENT	☐ BVM (± PEEP Valve) on Oxygen ☐ Waveform Capnography on BVM (minimum Colorimetric) ☐ ± Video Laryngoscope powered on ☐ ± Back-up Laryngoscope ETT, ETT size down, 2x Stylet, 2x Syringe, Tube Securing ☐ Bougie ☐ OPA, NPA, SGA (iGel, LMA, King LT) ☐ Nasogastric or Orogastric Tube ☐ Cricothyrotomy Kit ☐ Suction on and accessible

Rapid Sequence Intubation

CLINICAL INDICATIONS:

- Airway Compromise or Inability to Protect Airway
- Respiratory Failure (Hypoxic, Hypercapnic)
- Expected Clinical Deterioration
  - >40% TBSA Burns, Severe Sepsis, TBI with AMS, etc
- Patient or Crew Safety
  - Combative, prolong transfer in critically sick, etc

CONTRAINDICATIONS:

- High likelihood of failure (Distorted Anatomy)
- Penetrating neck trauma

PROCEDURE:

- Make a plan, prepare patient and equipment (See **PRE-INTUBATION CHECLIST**)

Conduct seven "P" pneumonic **(7Ps):**

PREPARE	☐ **SOAPME:** - Suction: available, check for function - Oxygen: Pre-Oxygenation + Apneic Oxygenation - Airways: ETT, SGA (iGel, King, etc), Cricothyrotomy - Pharmacology: Induction, Paralysis, Post-intubation Sedation - Monitor: BP, HR, RR, SpO2%, etCO2 capnography, 4-lead - Equipment: Bougie, Laryngoscope, Video Laryngoscope, Cric Kit ☐ **Difficult Airway Evaluation** (LEMON or HEAVEN Criteria) - Consider alternate airway, cricothyrotomy, or modify plan ☐ **Evaluate Cricothyrotomy Landmarks and Assess Procedural Difficulty**
PRE-OX	☐ **PreOxygenate / Denitrogenate** ≥ 3 minutes or 8 Vital Capacity Breaths with 15 LPM NRB or BVM + PEEP, and NC 4-6 LPM ☐ **Oxygenated ≥ 94%** - Patients remaining <94% may require CPAP or BVM + PEEP safe O2 saturation ☐ **Apneic Oxygenation with NC 15 LPM** once Induced/Sedated
POSITIONING	☐ **30° Head-up for Pre-Oxygenation** ☐ **Ear-to-Sternal Notch for Intubation** ☐ **C-Spine Consideration:** Open front of C-Collar; perform Manual In-line Stabilization
PRETREAT	☐ **Resuscitate** with IVF or Blood Products and Push-Dose Pressors to ensure SBP>100mmHg ☐ **3 - 5 Minute prior to Sedative / Paralytic** - **Fentanyl** 3mcg/kg slow IV push to prevent Hypertension in head injury, cardiac ischemia, or aortic dissection - **Atropine** 0.02 mg/kg IV to prevent bradycardia in Peds (age <1y)
PARALYZE / SEDATE	☐ **Push** Ketamine or Etomidate; and then Rocuronium or Vecuronium ☐ **Apneic Oxygenate:** Turn Nasal Cannula to 15LPM once patient becomes drowsy ☐ **Monitor SpO2%** and Wait 45-60 second for adequate paralysis
PASS TUBE	☐ **Visualize Cords and Pass Tube**
POST-TUBE MANAGEMENT	☐ **Inflate Bulb and Begin Bagging** ☐ **Verify Tube Place with etCO2 waveform capnography** - Direct visualization, mist in tube, equal rise and fall, bilateral breath sounds with absent gastric sounds, improving SpO2%, etCO2 colorimetric gold color change x6 ☐ **Secure Endotracheal Tube with commercial securing device** ☐ **Place patient on Post-intubation Sedation**

RSI MEDICATIONS

Induction Agents:

Ketamine 1-2 mg/kg IV
Etomidate 0.3 mg/kg IV
Midazolam 0.1 mg/kg IV
Propofol 1-2.5 mg/kg IV

Paralytics:

Rocuronium 0.6-1.2 mg/kg IV
Vecuronium 0.08-0.15 mg/kg IV
Succinylcholine 1.0-1.5 mg/kg IV

Maintenance Sedation:

Ketamine 0.5-2 mg/kg IVP or 0.5-2 mg/kg bolus then 0.5-1mg/kg/hr
Propofol 10-75 mcg/kg/min
Midazolam .05 mg/kg IVP or .05 mg/kg bolus then 0.05-0.1mg/kg/hr

Push Dose Epi:

Epinephrine 5-20mcg IV q2-5min

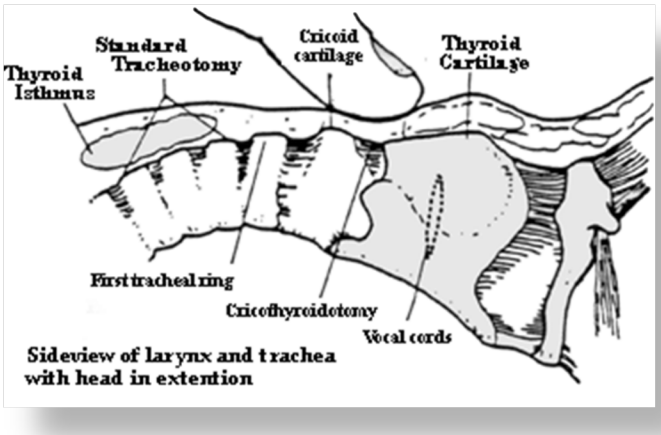
CRICOTHYROIDOTOMY

CLINICAL INDICATIONS:

- DIFFICULT AIRWAY- Airway can receive one (1) RSI attempt before calling it a failed airway. Two exceptions exist:
    - Inability to maintain proper O2 saturation above 90% or major trauma or obstruction
- NON-DIFFICULT AIRWAY- Airway can receive two (2) attempts so long as O_2 saturation is >90%.
- Inability to place / ventilate with blind insertion airway device (BIAD) or inability to provide ventilation with Bag-Valve mask.
- Massive facial trauma or neck trauma precluding the use of orotracheal intubation / BIAD.

CONTRAINDICATIONS:

- Age <12yo, abnormal anatomy. (See Needle Cricothyroidotomy)



PROCEDURE:

- Maintain patient in sniffing position or place them into sniffing position. Utilize inline stabilization if indicated.
- Oxygenate the patient with 100% O_2. Identify and cleanse the cricoid area with betadine / alcohol while oxygenating if possible.
- Before incising place static non-dominant hand using the middle and thumb to hold either side of the thyroid cartilage with the palm towards the head leaving and area between the fingers inferiorly to make the incision. This hand will not move until bougie is confirmed in the trachea.
- Using a scalpel, make an adequate (2-3cm) vertical incision over the cricothyroid membrane. Then, using hemostats, bluntly dissect until membrane fully visualized.
- Make an adequate horizontal incision through the cricothyroid membrane into the trachea. Spread incision with either hemostats or scalpel handle.
- At this point the index finger of the hand gripping the thyroid cartilage can be placed within the opening and the posterior aspect of the trachea can be palpated. The index finger maintains the tract should the airway be extremely bloody as this procedure is prone to be. The bougie/stylet is then placed along the index finger ensuring tracheal guidance and not subcutaneous plane dissection or posterior tracheal perforation into the esophagus.
- Once the bougie/stylet is inserted, pass a cricothyroid tube or 6-0 ETT into the trachea (if ETT used, only insert until just past the cuff, then inflate the cuff). Secure tube in place and begin to ventilate with BVM / 100% O_2.
- Confirm placement with capnography, capnometer, bilateral chest rise / breath sounds, good PO_2, $ETCO_2$, lack of increasing SQ air (a small amount is normal).
- **Document procedure, results, and vital signs.**

NEEDLE CRICOTHYROIDOTOMY

CLINICAL INDICATIONS:

- Child <10yo in whom open cricothyroidotomy is contraindicated with the following:
    - Failed intubation attempts x 3 by the most experienced provider present with inability to ventilate with BVM / high risk to ventilate with BVM.
    - Inability to place / ventilate with blind insertion airway device (BIAD).
    - Massive facial trauma or neck trauma precluding the use of orotracheal intubation / BIAD.

CONTRAINDICATIONS:

- Ability to ventilate adequately with BVM.
- Prolonged time to definitive care (relative).

NOTE: this technique requires a minimum of 50 psi O_2 or pressurized air flow and a special adapter to connect the line to the catheter hub; do not attempt otherwise.

PROCEDURE:

- Maintain patient in sniffing position or place them into sniffing position. Utilize inline stabilization if indicated.
- Oxygenate the patient with 100% O_2. Identify and cleanse the cricoid area with betadine / alcohol while oxygenating if possible.
- Using a 14Ga IV attached to a 3mL syringe, puncture the cricothyroid membrane at a 90º angle. **Do not advance needle once air returned.**
- Change angle to 45º and **advance Catheter only.** Should advance with no resistance. Remove needle and syringe.
- Secure catheter in place. Remove needle and plunger from syringe and place an adapter from a 7-0ETT on end of syringe in place of plunger. Attach this to the catheter.
- Attach a BVM attached to 100% O_2 to the adapter / syringe and ventilate. A large amount of resistance will be felt due to the small catheter size. Evaluate for chest rise and oxygenation. The provider needs to allow a 1:3 ratio of inhalation / exhalation.

Document procedure, results, and vital signs.

NOTE: Needle Cricothyroidotomy only allows for oxygenation, not ventilation. It is meant as a temporizing measure until definitive care – tracheostomy – can be performed at an MTF.
This airway should be used for only 20-30min maximum if able.

- Start working alternatives immediately after initiation - such as retrograde wire intubation, surgical cric with needle as an anatomical landmark.

SIMPLE (FINGER) and TUBE THORACOSTOMY

CLINICAL INDICATIONS:

- Pneumothorax + positive pressure ventilation or interfering with oxygenation
- Hemothorax + positive pressure ventilation or interfering with oxygenation
- Chest injury with suspected pneumo / hemothorax as above
- Evidence of tension pneumothorax after needle thoracostomy attempts

CONTRAINIDICATIONS:

- Stable patient oxygenating well, no tension PTX
- Blood clotting abnormalities (relative)

PROCEDURE (STERILE):

- Ensure all equipment prepared / available: Scalpel, 4X4 gauze, petroleum gauze, suture material (0 – 1-0 silk), 28Fr or larger chest tube, Heimlich valve / Water seal, large Kelly clamp x 2, betadine / skin cleanser, 1-2% lidocaine, 10mL syringe with needle for lidocaine, sterile gloves.
- If possible, position patient supine with shoulder flexed up and hand under his / her head.
- Identify and clean area of insertion with skin cleanser. Area of insertion should be over the 4th or 5th rib (3rd or 4th intercostal space) on injured side.
- If possible, with conscious patient, anesthetize the area with lidocaine. Take care to anesthetize the rib by passing needle perpendicular to skin until bone contacted and backing off slightly to inject lidocaine. May also anesthetize the pleura by advancing needle just until air returned and then injecting area while pulling back needle.
- Make incision in skin / SQ tissue overlying 5th rib. Ensure incision large enough for insertion of tube / finger (approximately 1-2 inch).
- Bluntly dissect tissue going over 5th rib with second clamp until pleura is reached, then puncture the pleura with the clamps. *Prevent overly deep insertion by using non-dominant hand to guide insertion or holding clamps in hand with index finger on shaft of the instrument.*
- Open clamps as wide as possible to enlarge the pleural opening and remove clamps. Blood and/or air may present at this time.
- Place finger into opening and palpate for any adhesions.
    - If Simple Thoracostomy **ONLY**, place vented chest seal over opening and position patient on ipsilateral side (if possible) and monitor for signs of tension pneumothorax.
    - If proceeding to tube placement, continue below ensuring tube is clamped closed on distal end before insertion.
- Advance tube into opening directing the tip of the tube posteriorly and superiorly towards the lung apex along the posterior aspect of the chest wall, ensuring all fenestrations are moved into opening. This method ensures tube will drain both hemo and pneumothoraces.
- Holding tube in place – Pad under tube with Kerlix and place modified chest seal around the tube ensuring seal of the wound and securing tube in place. If possible, stitch or staple tube into place.
- Apply suction to tube / Heimlich valve and remove clamp.

Document procedure, results, and vital signs.

CHEST TUBE TROUBLESHOOTING:

- Ensure tube not clamped / kinked and that suction is working.
- Ensure tube has not become dislodged.
- If evidence of tension PTX – remove attachments from end of chest tube (e.g., suction adapter, Heimlich valves, suction devices) to convert to open PTX. Troubleshoot attachments and re-apply if appropriate.

NEEDLE THORACOSTOMY

CLINICAL INDICATIONS:

Suspect a tension pneumothorax and treat when a casualty has significant torso trauma or primary blast injury and one or more of the following:

- Severe or progressive respiratory distress or tachypnea, absent or markedly decreased breath sounds on one side of the chest, chest pain, distended neck vessels, hemoglobin oxygen saturation < 90% on pulse oximetry, shock, traumatic cardiac arrest without obviously fatal wounds

* Note: If not treated promptly, tension pneumothorax may progress from respiratory distress to shock and traumatic cardiac arrest.

CONTRAINDICATIONS:

- None

PROCEDURE: **Note: This intervention is a BRIEF stopgap utilized in order to buy time for a definitive tube thoracostomy. It is not a solution unto itself.**

- Decompress the chest on the side of the injury with a 14-gauge or a 10-gauge, 3.25-inch needle/catheter.
- If a casualty has significant torso trauma or primary blast injury and is in traumatic cardiac arrest: decompress both sides of the chest before discontinuing treatment. Clean area if possible with betadine / alcohol, but do not delay treatment for this step.

Note: Either the 5th intercostal space (ICS) in the anterior axillary line (AAL) or the 2nd ICS in the mid-clavicular line (MCL) may be used for needle decompression (NDC.) If the anterior (MCL) site is used, do not insert the needle medial to the nipple line.

- The needle/catheter unit should be inserted at an angle perpendicular to the chest wall and just over the top of the lower rib at the insertion site. Insert the needle/catheter unit all the way to the hub and hold it in place for 5-10 seconds to allow decompression to occur.
- After the NDC has been performed, remove the needle and leave the catheter in place.
- The NDC should be considered successful if:
    - Respiratory distress improves; there is an obvious hissing sound as air escapes from the chest when NDC is performed (this may be difficult to appreciate in high-noise environments); hemoglobin oxygen saturation increases to 90% or greater (note that this may take several minutes and may not happen at altitude); casualty with no vital signs has return of consciousness and/or radial pulse.
- If the initial NDC was successful, but symptoms later recur:
    - Perform another NDC at the same site that was used previously. Use a new needle/catheter unit for the repeat NDC.
- If the second NDC is also not successful:
    - Fix appropriate circulation issues and consider finger/tube thoracostomy.

Document procedure, results, and vital signs.

VENTILATOR MANAGMENT

CLINICAL INDICATIONS:

- Patient received from transferring facility, intubated, and requires ventilator support.
- Patient requiring intubation in the field and subsequent respiratory support.

CONTRAINDICATIONS:

- Equipment malfunction / failure.

PROCEDURE:

- Turn on ventilator and ensure that machine is functional and battery is charged.
- Attach ventilator tubing and O_2 tubing to machine.
- If patient is a transfer and already on vent, maintain ventilator settings from medical treatment facility.

If patient "newly" on ventilator, initial settings include:

- **Mode:** Assist Control (AC) / CMV+ or ASV (Hamilton T1 only). AC / CMV+ are the preferred modes over ASV.
- **Tidal Volume (Vt):** Initially 6 cc/kg, (Ideal Body Weight (IBW) then adjust based on ventilatory needs (4-8 cc/kg)
    - IBW calculation for Predicted Body Weight in Kg:
        - Men: [(height in inches – 60) x 2.3] + 50
        - Women: [(height in inches – 60) x 2.3] + 45.5.
    - ***Tidal Volume should not be altered to fix ventilation, adjust rate instead for increased or decreased minute volumes***! Vt only gets changed for lung protection (i.e. to prevent barotrauma/volutrauma)
    - Reduce VT by 1 ml/kg at intervals ≤ 2 hours until VT = 6cc/kg PBW
    - SEE PBW Tidal Volume Chart Below
- **Rate (RR):** Initially 14, adjust based on CO2 (If CO2 >45mmHg) and ventilatory needs (10-30)
- **I:E:** 1:2 (Patients with obstructive lung diseases should have increased I:E around 1:4 or 1:5; If rate > 20 (most children) will need to titrate iTime down to achieve appropriate I:E ratio)
- **FiO2/PEEP (Should be adjusted in concert per the chart below)**
    - Start at 100% (1.0) FiO2 and PEEP of 5; PEEP no higher than 16 on Pediatrics w/out expert consult
    - Wait 5 minutes and assess SpO2

PA.10 Simple & Tube Thoracostomy
PA.11 Needle Thoracostomy
PA.12 Ventilator Management
PA.123 754 Preflight and Troubleshooting
PA.14 731 Preflight and Troubleshooting
PA.15 COVID-19 Management
PA.1p Pediatric Airway
PA.2 Airways Pearls
PA.3 Airway Confirmation
PA.4 BIAD
PA.5 Failed Airway
PA.4 Nasopharyngeal Airway
PA.7 Rapid Sequence Intubation
PA.7a Pre-intubation Checklist
PA.8 Cricothyroidotomy
PA.9 Needle Cricothyroidotomy

- Set the FiO2 to 30% and start titrating FiO2 and PEEP collectively based on the chart to achieve oxygenation goals. Go up every 5-10 minutes; quicker if low SpO2 sats develop.

Lower PEEP/higher FiO2

FiO_2	0.3	0.4	0.4	0.5	0.5	0.6	0.7	0.7
PEEP	5	5	8	8	10	10	10	12

FiO_2	0.7	0.8	0.9	0.9	0.9	1.0
PEEP	14	14	14	16	18	18-24

*** Hypotensive patients (MAP <70 or SBP <90) may respond negatively to increased PEEP causing decreased venous return. Monitor for increased hypotension and tachycardia.**

- **Alternate Higher PEEP settings**

Higher PEEP/lower FiO2

FiO_2	0.3	0.3	0.3	0.3	0.3	0.4	0.4	0.5
PEEP	5	8	10	12	14	14	16	16

FiO_2	0.5	0.5-0.8	0.8	0.9	1.0	1.0
PEEP	18	20	22	22	22	24

- **Oxygenation Goal:** PaO2 55-80 mmHg or SpO2 88-95%
- **Plateau Pressure Goal: ≤ 30 cm H2O**
  - Check Pplat (0.5 second inspiratory pause), at least q 4h and after each change in PEEP or VT.
  - **If Pplat > 30 cm H2O:** decrease VTby 1ml/kg steps (minimum = 4 ml/kg).
  - **If Pplat < 25 cm H2Oand VT< 6 ml/kg**, increase VT by 1 ml/kg until Pplat > 25 cm H2O or VT = 6 ml/kg.
  - **If Pplat < 30 and breath stacking or dys-synchrony occurs:** may increase VT in 1ml/kg increments to 7 or 8 ml/kg if Pplat remains < 30 cm H2O.
- **Alarm Settings:**
  - **High Pressure Alarm:** 10 cmH20 above peak airway pressure
  - **Low Pressure Alarm:** 5 cmH2O below peak airway pressure

    or
  - **High Pressure Alarm** 50% above the baseline PIP (1.5 x current PIP)
  - **Low Pressure Alarm** 50% below the baseline PIP (0.5 x current PIP)

    ** *Pressures will be determined by placing patient on vent for ~1-2 minutes and determining intrinsic peak inspiratory pressure. (Labeled as PEAK on 754 Ventilator (top right); Labeled as Ppeak on Hamilton T1 ventilator (top left).*
- Monitor waveform on machine and patient to ensure not "breathe stacking" – if this occurs, a high-pressure alarm may sound. However, if breath stacking suspected even in absence of alarm – disconnect tubing and allow exhalation. Increase I:E.

Predicted Body Weight and Tidal Volume (V_T)

Male PBW and Tidal Volume							
Height		Predicted Body Weight	ml per kg of PBW (total V_T)

PBW Males = 45.5 + 2.3 [height (inches) - 60]

ARDSnet, NIH NHLBI ARDS Clinical Network Mechanical Ventilation V_T card

Troubleshooting: Airway compromise or lost airway in-flight

- If at any time patient begins to desaturate or develop respiratory problems, immediately disconnect ventilator and ventilate patient with BVM (with PEEP valve if available) and 100% O_2 while correcting issues utilizing the **D.O.P.E.** algorithm:
    - **Displacement:** ETT in place, patient not extubated/ tube did not move during transfer. If advanced – pull back to original length and attempt to bag; if tube has pulled farther out of trachea, DO NOT ATTEMPT TO ADVANCE IT without placement of bougie to verify tracheal placement. When advancing bougie, feel for tracheal rings or carina stop. If in doubt, pull tube and attempt BVM. If this fixes problem, continue to bag patient. Upon stabilization, consider alternative advanced airways (extraglotic airway or cric).

      ****If ETT moves freely, access for ETT bulb rupture.**
    - **Obstructions:** Assess for secretions in ETT. Suction if indicated.
    - **Pressure:** Ensure that a tension pneumothorax / hemothorax has not developed (if chest tube in place, ensure it is functioning/ not kinked or clamped). If tension pneumo/hemothorax suspected, perform immediate needle thoracostomy. Assess the need for escarotomy if circumferential burn. Consider additional paralysis and sedation if patient does not tolerate ventilation.
    - **Equipment:** Ensure that vent did not fail; O_2 tank not empty. If ventilator is operational, trace all tubes to the patient connection (airway tube, transducer line, exhalation line) ensuring patency and connections.

- **High pressure alarms / Peak airway pressure alarms** (Peak pressure >35 cm H_2O): Correct problems causing increased airway resistance and decreased lung compliance, including pneumothorax or pulmonary edema. Check ventilator to make sure prescribed tidal volume is being delivered. Check for linked/crushed tubing.
- **Air leaks causing low pressure alarms / volume loss**: Assess, correct air leaks in endotracheal tube, tracheostomy cuff, ventilator system; recheck ventilator to make sure prescribed tidal volume is delivered.
- **Ventilator desynchrony**: Agitation and respiratory distress that develop in a patient on a mechanical ventilator who has previously appeared comfortable represents an important clinical circumstance that requires a thorough assessment and an organized approach. The patient should not always be automatically re-sedated but must instead be evaluated for several potentially life-threatening developments that can present in this fashion.
- **Lung hyperinflation (air trapping) and auto-PEEP:** Dynamic hyperinflation is associated with positive end-expiratory alveolar pressure, or auto-PEEP. The physiologic effects include decreased cardiac preload because of diminished venous return into the chest. The reduced cardiac output that results from the reduction in preload can lead to hypotension and, if severe, to Pulseless Electrical Activity and cardiac arrest. Dynamic hyperinflation can also lead to local alveolar over-distention and rupture. Prevent, manage lung hyperinflation by decreasing tidal volume, changing inspiratory and expiratory phase parameters, switching to another mode, and correcting physiological abnormalities that increase airway resistance.

- **Document procedure, results, and vital signs.**

Ventilator Transfer Procedure

1. Ensure endotracheal tube is secure, document size and position of ETT at the teeth. Clamp tube immediately before disconnecting patient from vent in order to maintain PEEP and un-clamp only after connected to new vent circuit.

2. Ventilator settings should be coordinated with the transferring physician, anesthesia provider or respiratory therapist. Verify settings, review arterial blood gas (ABG) analysis, and current SPO_2 and $ETCO_2$ readings. Place those setting on transport vent and place patient on transport vent early to verify patient tolerance and compatibility.

3. ABG should be done within 30 minutes of flight. If time allows, patient should be on transport ventilator for at least 15 minutes prior to transport.

4. Ventilator settings for en-route care team should initially be matched to those of the transferring facility. Adjust settings PRN in order to maintain appropriate clinical parameters listed on first page of ventilator management protocol or transferring physician orders.

5. Ensure adequate sedation and analgesia medications are on hand.

VENTILATOR Terms

Volume-targeted modes: (Examples**: CMV** Continuous Mandatory Ventilation, **A/C** Assist/Control, **SIMV** Synchronized Intermittent Mechanical Ventilation) - Volume constant, inspiration terminates when preset V_t delivered. Peak airway pressure is variable and increases as needed to deliver prescribed V_t.

Pressure-targeted modes: (Examples: **PSV** Pressure Support Ventilation**, PCV** Pressure Controlled ventilation) - Volume variable, terminates when preset pressure reached. Volume is variable. Peak airway pressure is fixed, determined by set pressure level.

Adaptive Support Ventilation (ASV): Only available on the Hamilton T1. ASV provides intelligent ventilation mode that continuously adjusts respiratory rate, tidal volume, and inspiratory time depending on the patient's lung mechanics and effort.

Tidal volume (V_t): The volume of gas, either inhaled or exhaled, during a breath and commonly expressed in milliliters. V_t is generally set between 4-8ml/kg IBW (ideal body weight), to prevent lung over-distension and barotrauma.

Minute Ventilation (V_E): The average volume of gas entering, or leaving, the lungs per minute, commonly expressed in liters per minute. The product of V_t and RR (respiratory rate). Normal V_E is 5 – 10 L/min.

Inspiratory (I) **and Expiratory** (E) **time and I:E ratio**: The speed at which the V_t is delivered. Setting a shorter inspiratory time (I) results in a faster inspiratory flow rate. Average adult I time is 0.7 to 1 second. I:E ratio is usually 1:2 to 1:4

Positive end-expiratory pressure (PEEP): The amount of positive pressure that is maintained at end-expiration. It is expressed in centimeters of water. The purpose of PEEP is to increase end-expiratory lung volume and reduce air-space closure at end-expiration. Normal Physiologic PEEP is 5cm/H_2O.

Peak flow rate or peak inspiratory flow: The highest flow, or speed, that is set to deliver the V_t during inspiration, usually measured in liters per minute. When the flow rate is set higher, the speed of gas delivery is faster and inspiratory time is shorter.

Peak Airway Pressure (P_{AW}): Represents the total pressure that is required to deliver the V_t and depends upon various airway resistance, lung compliance, and chest wall factors. It is expressed in centimeters of water (cm H_2O).

Sensitivity or trigger sensitivity: Effort, or negative pressure, required by the patient to trigger a machine breath, commonly set so that minimal effort (-1 to -2 cm H_2O) is required to trigger a breath.

Provide Continuous Positive Airway Pressure (CPAP/BiPAP)

Contraindications: Suspected Pneumothorax, SBP < 90mmHg, facial trauma, lack of airway protective reflex (unconscious) respiratory or cardiac arrest, vomiting or active upper GI bleed

1. If possible, place patient in seated position and explain the procedure.

2. Perform an initial respiratory assessment and assess vital signs.

3. Use the mask-sizing gauge to measure the patient for the correct mask size and attach the mask to the circuit.

Note: The mask selected should come close to, but not in contact with the nasal bone, external nares, and upper lip.

4. Turn the unit on and operate device according to manufacturer's specifications.

    Initial settings: CPAP 5 cm H2O

    Initial settings: BiPAP 10 cm H2O/ 5 cm H2O

    Adjusted on most ventilators by using PEEP input button

5. Place the head straps on the patient IAW the manufacturer's instructions. Check for leaks and readjust if necessary.

6. Initiate positive airway pressure and adjust the CPAP/BiPAP pressure with the lowest continuous pressure that is effective.

7. Perform a respiratory assessment and titrate treatment to physiological goal.

8. Monitor patient continuously, assess and record vital signs at a minimum of every 5 minutes.

9. Observe for signs of deterioration or failure to respond to CPAP/BiPAP.

10. Consider low-dose benzodiazepine for anxiety and mask tolerance.

IMPACT 754 Ventilator Pre-mission checks and Troubleshooting

Routine Care

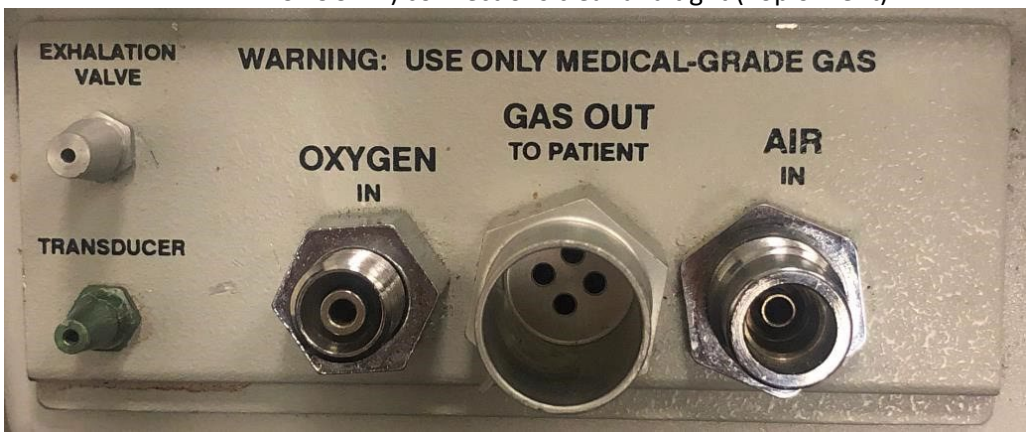
Clean unit and hose attachments with damp soapy cloth and wipe dry. Inlet filter may be removed to check for dirt or debris. Check metal hose couplings for thread wear and debris.

Duty Inspection

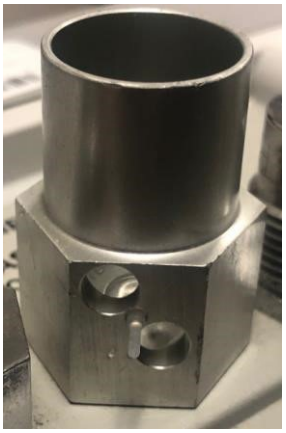
1. Power Off Checks
   a. Within calibration date (6 month maintenance cycle)

   b. Air inlet clear and filter in place (Right side of vent)

   c. Gas ("OXYGEN IN" and "AIR IN") and Patient ("EXHALATION VALVE" and "TRANSDUCER") connections clear and tight (Top of vent)



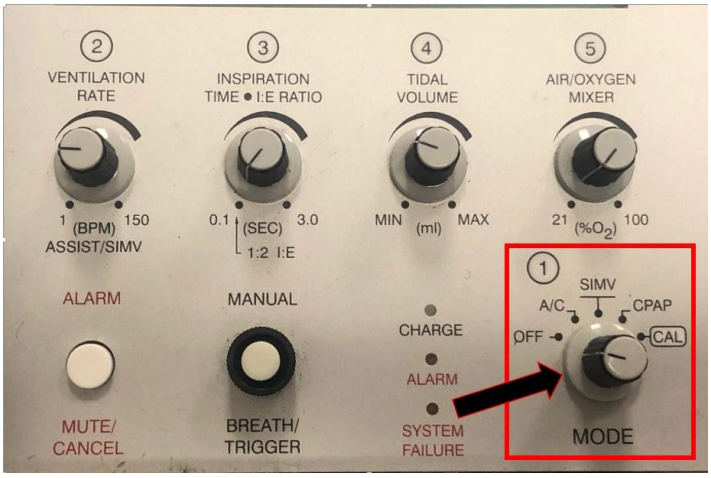
d. GAS OUT clear leaf valve installed and seated (Reseat if loose, Replace if missing) See replacement instructions at the end of this document.



e. Inspect green high pressure oxygen hose for cracks, dry rot, threads, Black O-ring (Replace if damaged).

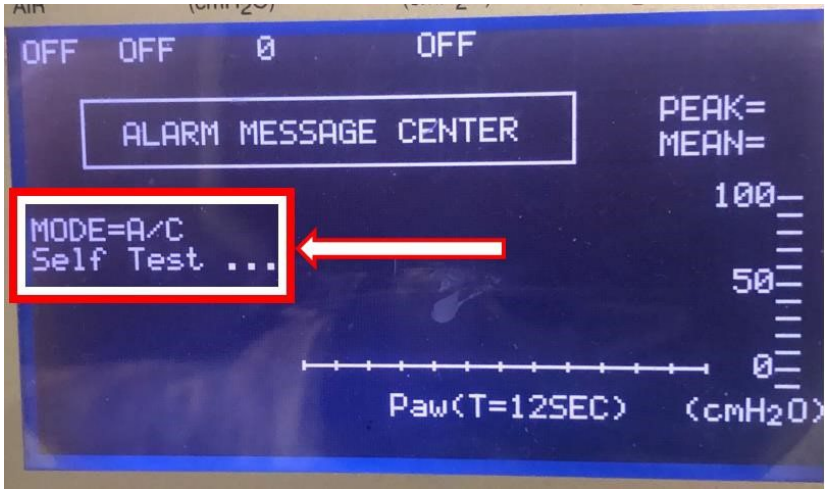
f. Connect ventilator to high pressure oxygen source, turn on Oxygen tank and ensure no leaks present. Turn off O2 when complete. (Conduct in environment conducive to hearing leaks)

2. Power On Checks
   a. Turn “MODE” knob (1) to desired setting (A/C, SIMV, CPAP)

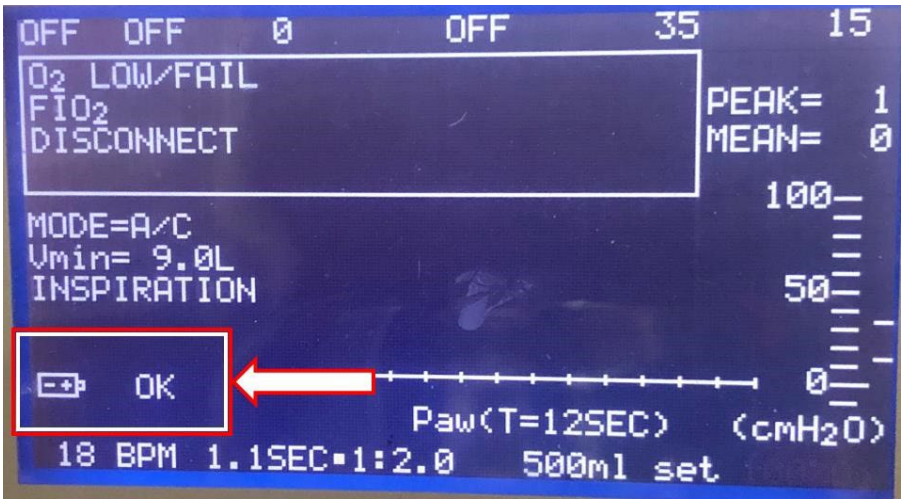


i. The ventilator will run a SELF-TEST upon set up. **CAUTION:** *SELF-CHECK must be performed with the disposable ventilator circuit disconnected. Ignoring this requirement could cause the SELF- CHECK process to sense a residual airway pressure leading to a SELF-CHECK failure*.

1. At this point, CAL is not required. If SELF-TEST results in a Calibration Failure, place (1) to CAL until CAL OK is displayed. If calibration fails, ventilator is deadlined.



b. Check BATT OK



c. Preset ventilator knobs to:

i. Rate (2) 18
ii. Inspiration Time (3) 1:2
iii. Vt (4) 500
iv. FiO2 (5) 100%
v. HIGH pressure alarm to 35 cmH2O vi. LOW pressure to 15 cmH2O

d. Turn OFF

e. Store Ventilator with Air Inlet and Gas Out Ports protected and covered.

Ventilator is now pre-set for duty and able to be rapidly employed as needed with minor adjustments to Vt based on patient ideal body weight and turning on O2 source

Weekly Inspections

ALL CAUTIONS, WARNINGS, AND NOTIFICATIONS THAT CORRESPOND WITH THE 754 SCREEN WILL BE IN ALL CAPS AND HIGHLIGHTED YELLOW

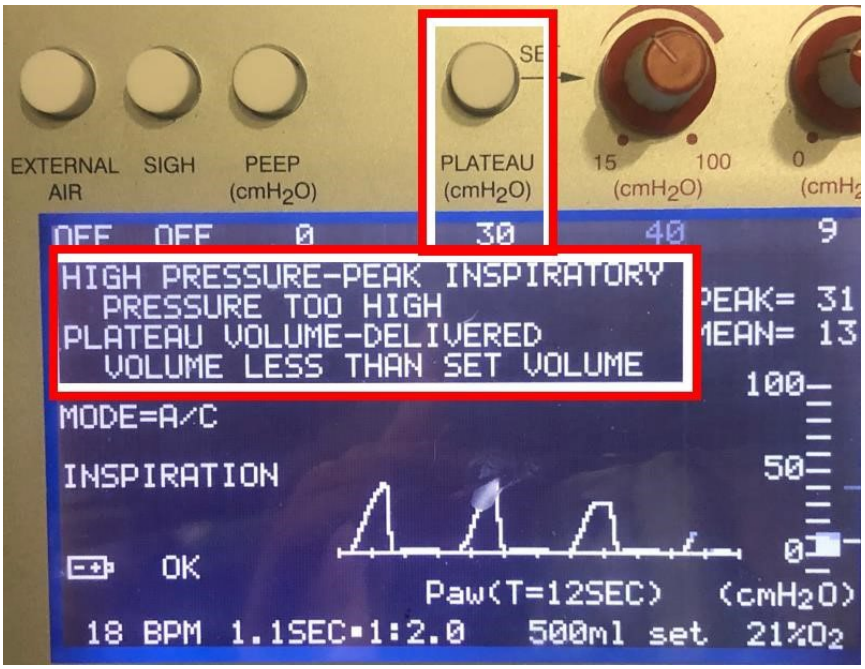
1. Complete Duty Inspection
2. Set FiO2 to 21%
3. Attach vent circuit to vent and field expedient training lung:
    a. Slide one large exam glove inside another.
    b. Wrap open end of the gloves around the patient end of the circuit tube.
    c. Secure with rubber band (DD1380) / Cut-off wrist bead of another glove / Penrose drain / Tape

4. Connect high pressure oxygen source and turn on O2
5. Turn vent on and allow respirations to begin (listen for compressor)
6. Set FiO2 to 100%
    a. Internal compressor will stop (audible)
7. Turn off oxygen source
    a. Ventilator will alarm and show
    b. "O2 LOW/FAIL-CHECK OXYGEN SOURCE/CONNECTIONS" and "FIO2-GAS MIX ERROR. CHECK SOURCE/SETTINGS/CONNECTIONS"
    c. Compressor will turn on (audible)

8. Set FiO2 to 21%.
9. Set HIGH pressure alarm to 5 cmH2O **below** PEAK.
    a. Ventilator will "stutter" and show "HIGH PRESSURE-PEAK INSPIRATORY PRESSURE TOO HIGH" warning and signal an alarm.

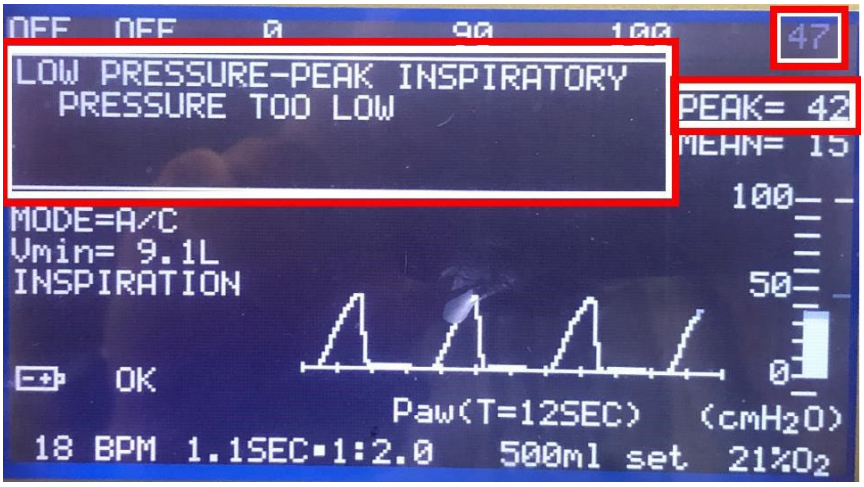
10. Turn PLATEAU pressure ON

    a. Ventilator will display "HIGH PRESSURE-PEAK INSPIRATORY PRESSURE TOO HIGH" and "PLATEAU VOLUME-DELIVERED VOLUME LESS THAN SET VOLUME" and trigger an alarm.



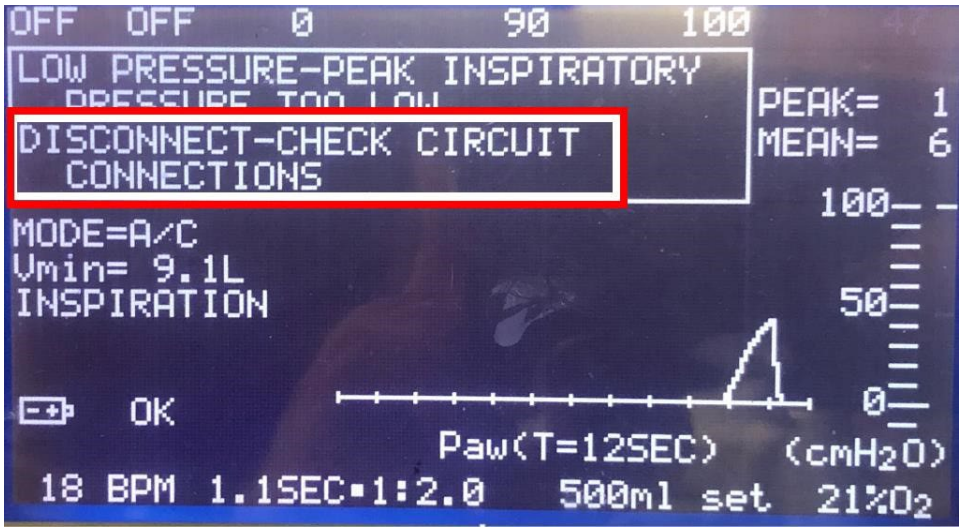
11. Turn HIGH Pressure alarm to 100.

12. Set LOW pressure alarm to 5 cmH2O **above** PEAK
    a. Ventilator will display "LOW PRESSURE-PEAK INSPIRATORY PRESSURE TOO LOW" and trigger an alarm.



13. Remove circuit from ventilator.

    a. Ventilator will display "DISCONNECT-CHECK CIRCUIT CONNECTIONS" and trigger an alarm.



14. Preset ventilator for use per Duty Inspection Power On Checks and turn off.

IN-FLIGHT EMERGENCY

*****These procedures should be practiced before performed on live patients*****

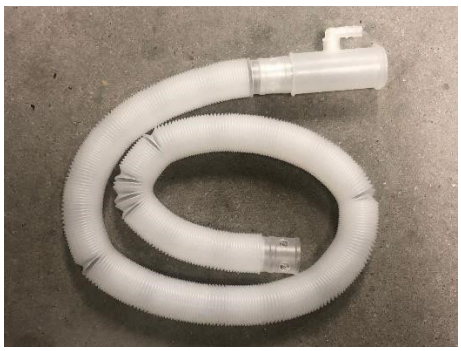
****Any known malfunction of ventilator should be addressed prior to flight. The following are not for routine use but for emergencies when alternate ventilitory measures are not available and long term BVM is not practical****

 Loss of high pressure O2 delivery when needs exceed 21% FiO2 (i.e. missing/unserviceable green high pressure hose.) will alarm and show "O2 LOW/FAIL-CHECK OXYGEN SOURSE/CONNECTIONS" on screen

NOTE: First Place Patient on BVM with supplemental O2. Second, check oxygen tank volume. Third, check the O2 lines and connections

Alternative methods to increase delivered oxygen content

1. Commercial oxygen reservoir kit for low pressure supply is available (Part # 820-0097-15)

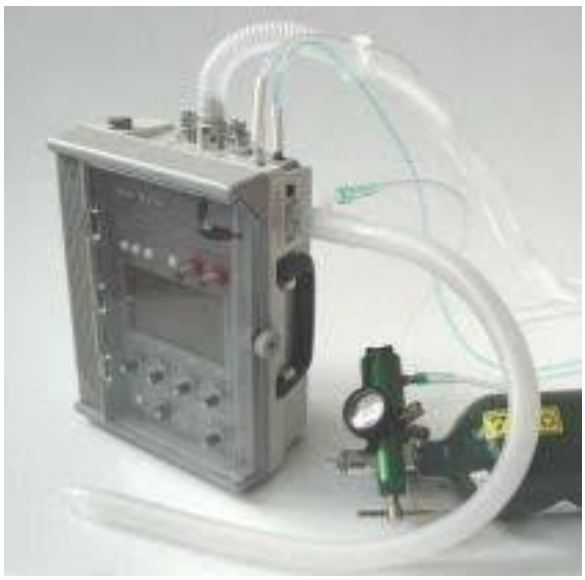


2. Oxygen reservoir fashioned from primary circuit and BVM
    a. Connect short portion of main circuit tube to the BVM and to the airinlet port.
    b. Connect BVM O2 hose to the BVM and the regulator.
    c. Set regulator to desired setting (~10LPM, but no lower than total minute volume.

3. Oxygen reservoir fashioned from second ventilator patient circuit.
    a. Cut/disconnect exhalation valve off of second ventilator circuit.
    b. Remove transducer fitting from exhalation valve at attach it to the main circuit.

c. Connect the transducer hose to the original transducer fitting and the other end to regulated oxygen source.
d. Connect the transducer fitting (still attached to the circuit) to the air inlet port.
e. Set regulator on O2 source to 10 LPM to deliver up to 99% FIO2.

NOTE: Ventilator circuit tubing will provide reservoir for 650-700 ml of O2. Vt of greater than 650-700ml may result in lower FIO2.



Missing or damaged "GAS OUT" leaf valve

1. Missing "GAS OUT" leaf valve will trigger an alarm, give a "DISCONNECT- CHECK CIRCUIT CONNECTIONS", no "PEAK" value will display, and little to no volume will be delivered to patient.

    a. Place patient on BVM with supplemental O2
    b. Perform DOPE (Dislodgment, Obstruction, Pneumothorax, and Equipment) assessment.
    c. Check "GAS OUT" leaf valve for installation and proper seating.
        i. If folded, use small object to gently unfold or push valve back into place
        ii. If missing, replace ventilator immediately if able. If unable to replace, cover GAS OUT side ports with occlusive dressing. (Replacing GAS OUT leaf valve is optimal but time consuming.)

WARNING: Occluding GAS OUT side ports will enable ventilator to provide full respirations, however, this will eliminate the antiasphyxia function these ports provide (Ventilator failure will result in increased resistance in spontaneous respiration) and strict surveillance must be kept on ventilator to ensure any further failure is caught immediately. Patient must immediately be transitioned to BVM in the event of any failure.

Compressor failure/alarms (may show CODE 2)

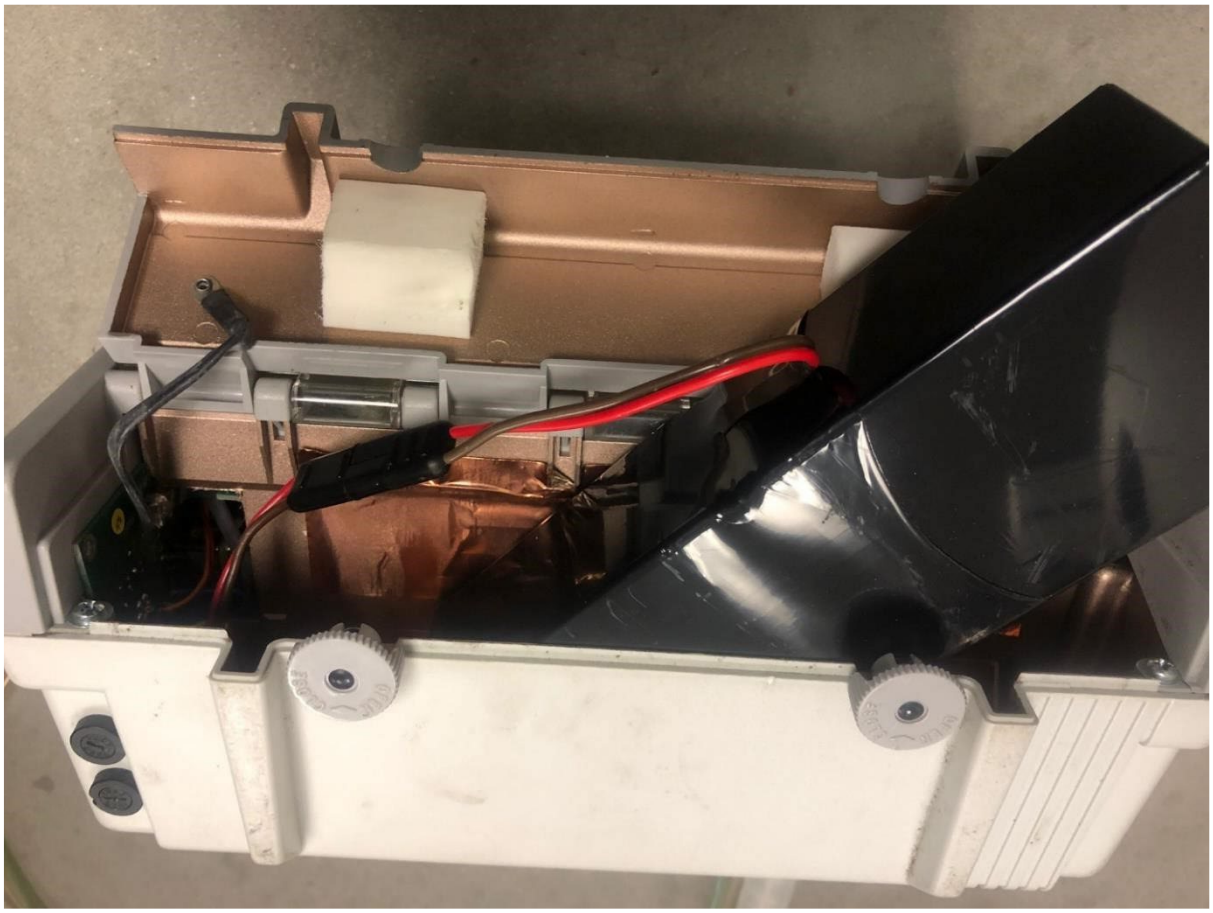
1. Place patient on BVM with supplemental O2
2. Cycle ventilator to OFF

3. Turn FiO2 knob (#5) to 100%
4. Cycle back on and to desired settings leaving FiO2 at 100%
    a. PEEP will have to be reset when vent is cycled on.

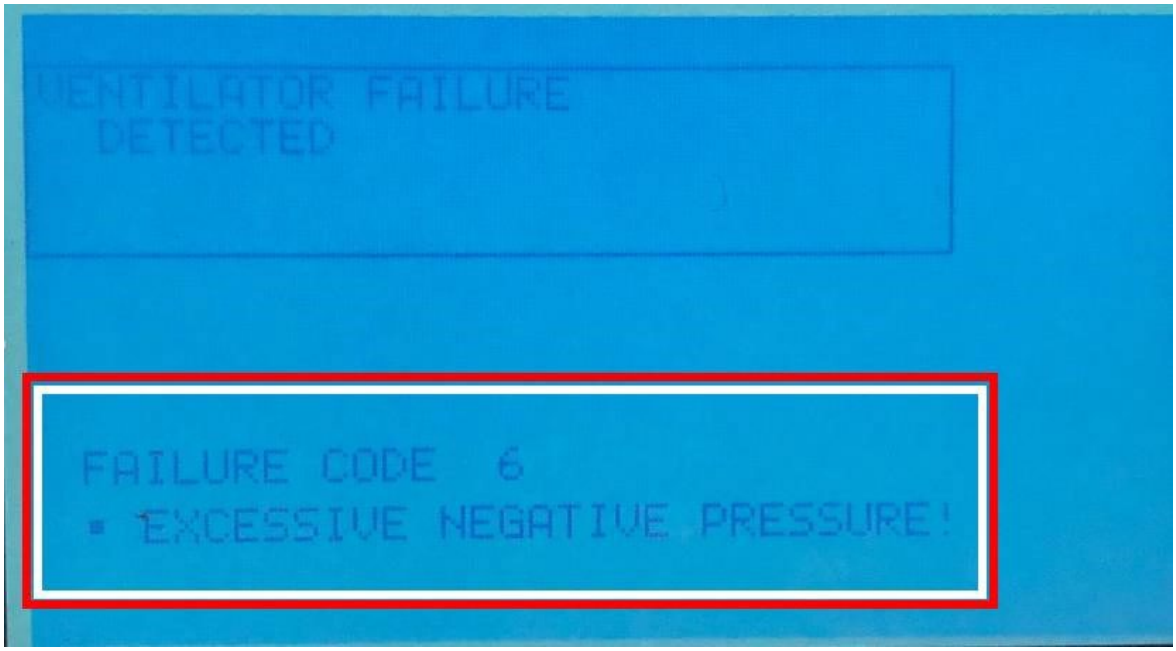
Note: This technique will transition the ventilator to using oxygen pressure instead of the compressor to drive ventilation and may hasten oxygen usage

 Battery Failure

1. Place patient on BVM with supplemental O2
2. Turn ventilator OFF
3. Replace ventilator battery with battery from 326M suction apparatus. (Per the manufacturer, they are the exact same!)
    a. 326M battery is in the same location as the 754.
4. Resume normal operations
    a. PEEP will have to be reset when vent is cycled on.



Fail Code 6
Suctioning to long with inline suction and/or patient inspiratory effort is significant enough to trigger.

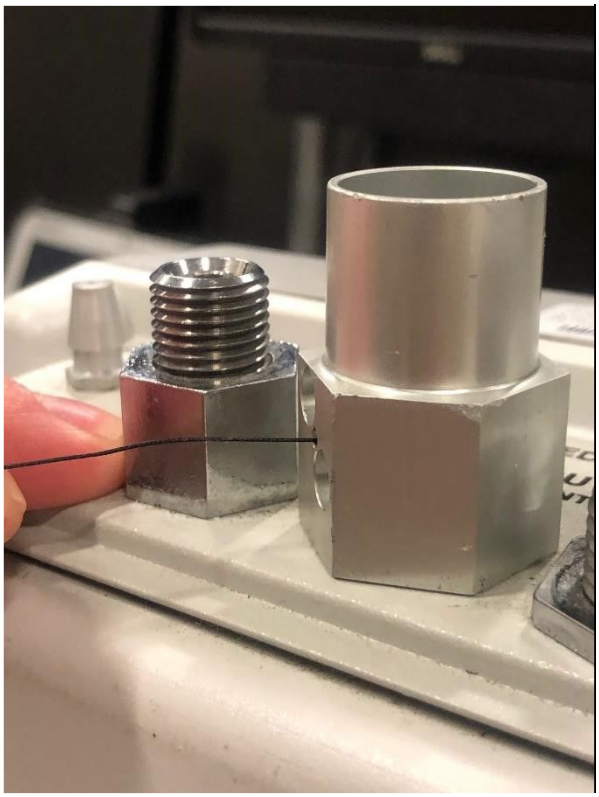


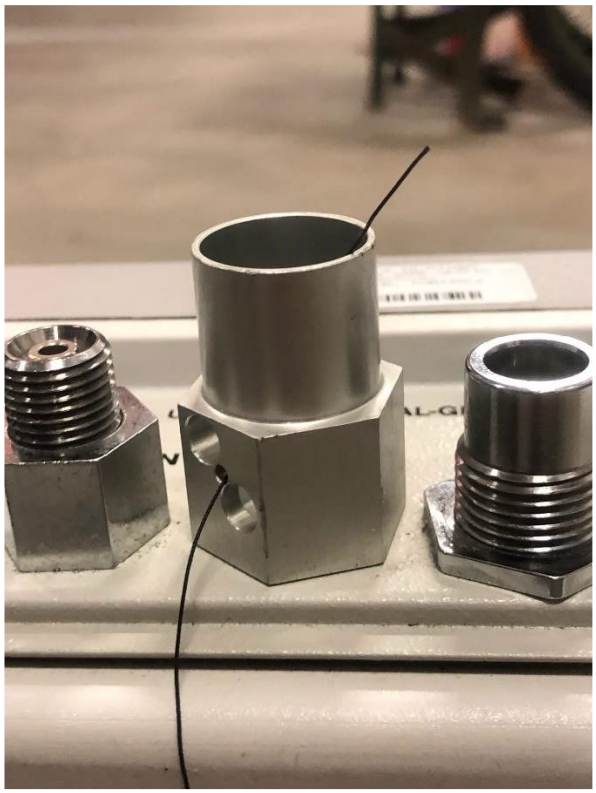
1. Place Patient on BVM with O2
2. Assess Patient
3. Cycle Vent off and on (will have to reset Peep)
4. Check vent settings
5. Place patient on ventilator

Document all failures of equipment and solutions on DD1380, DA4700, and in Joint Patient Safety Reporting (JPSR) registry https://health.mil/Military-Healthhttps://health.mil/Military-Health-Topics/Access-Cost-Quality-and-Safety/Quality-And-Safety-of-Healthcare/Patient-Safety/Joint-Patient-Safety-ReportingTopics/Access-Cost-Quality-and-Safety/Quality-And-Safety-of-Healthcare/Patienthttps://health.mil/Military-Health-Topics/Access-Cost-Quality-and-Safety/Quality-And-Safety-of-Healthcare/Patient-Safety/Joint-Patient-Safety-ReportingSafety/Joint-Patient-Safety-Reporting

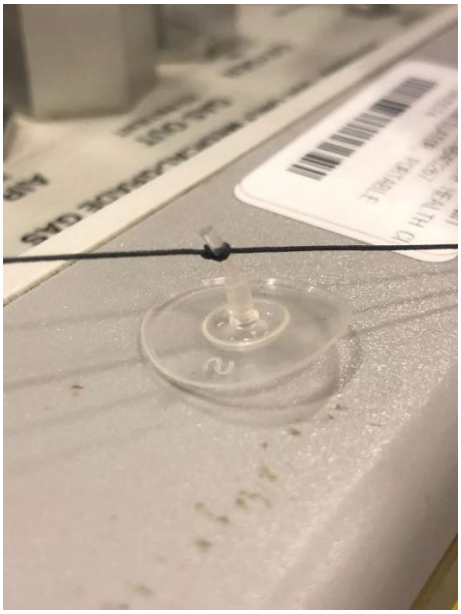
REPLACING GAS OUT LEAF VALVE

1 . Feed suture through small center hole.





2. Tie small square knot over end of tail of leaf valve.



3. Pull gentle tension on suture while guiding the leaf valve into place.

4. Maintain gentle traction against suture while applying pressure against the leaflet valve inside gas port with finger. Remove string once valve is seated. (Use caution to not apply too much tension to suture as leaf valve tail can tear.)

ALTERNATIVE FOR MISSING INTERNAL COMPRESSOR AIR FILTER

Ventilator inspiratory bacteria filter can be attached to air inlet (Missing air filters allow dust, debris, and/or moisture to be pulled into the ventilator compressor. This results in increased work-load of the ventilator leading to diminished battery life and eventual compressor failure)

Common Replacement Parts

Zoll/ NSN Part Numbers

-Zoll Part #: 820-0097-15 Oxygen reservoir kit for low pressure supply

-MEDSILS: OXYGEN ADAPTER BLEED-IN RESERVOIR FOR VENTILATORS

ZOLL 731 Ventilator Pre-mission Checks and Troubleshooting

Routine Care

- Keep the ventilator and its accessories clean at all times.
- Clean the unit's housing and hose connections with a damp, soap cloth
- For general decontamination, apply a 10% bleach solution with a damp cloth.
- After cleaning, thoroughly dry the unit with a lint free cloth. Make sure all exposed surfaces are cleaned and dried.

Duty Inspection

- Ensure the ventilator is clean and free of visible damage
- Inspect all accessories and connectors for signs of damage or excessive wear. Replace worn or defective items.
- Examine high pressure hose for cracking, discoloration, or disfigurement. Examine end connection fittings for damaged threads and sharp edges. Replace worn or defective hoses. *DO NOT attempt to repair hoses
- Examine the ventilator circuit for damage or wear including cracking or discoloration. If there are signs of physical degradation or the unit is indication ventilator circuit problems, replace the circuit
- Examine the filters and replace them if dirty of clogged
- Inspect the external AC/DC adapter, line cords, and DC power cables for wear or damage. Replace if worn or damaged.

*Recommended to use a disposable external filter when operating in areas where fine dust or dirt is airborne due to wind.

* The Zoll Ventilator can operate over the range of -25 to 49 degrees Celsius in emergency situations. When operating at high temperatures, you should remove the unit from its padded case, which allows the unit to pass heat into the surrounding environment.

Operational Test

Before attaching the patient to the ventilator, you must perform an Operational Test to ensure that the breathing circuit is properly attached and that the primary patient safety alarms, such as PATIENT DISCONNECT and AIRWAY PRESSURE HIH, are functioning properly.

1. Press the MANUAL BREATH button; gas should flow out of the patient connection each time the button is pressed.

2. Close the patient port with a gloved hand. During inspiratory phase, the HIGH AIRWAY PRESSURE LIMIT alarm should activate after 2 breaths.

a. If the AIRWAY PRESSURE HIGH alarm fails to activate, ensure all the tubing connections are secure, the exhalation valve is closing during inhalation, and that the High Airway Pressure Limit is set to 35 cm H2O or less.

3. After a breath or two, release the patient port while allowing the ventilator to operate. The PATIENT DISCONNECT alarm should activate.

4. Partially close the patient port to reset the PATIENT DISCONNECT alarm.

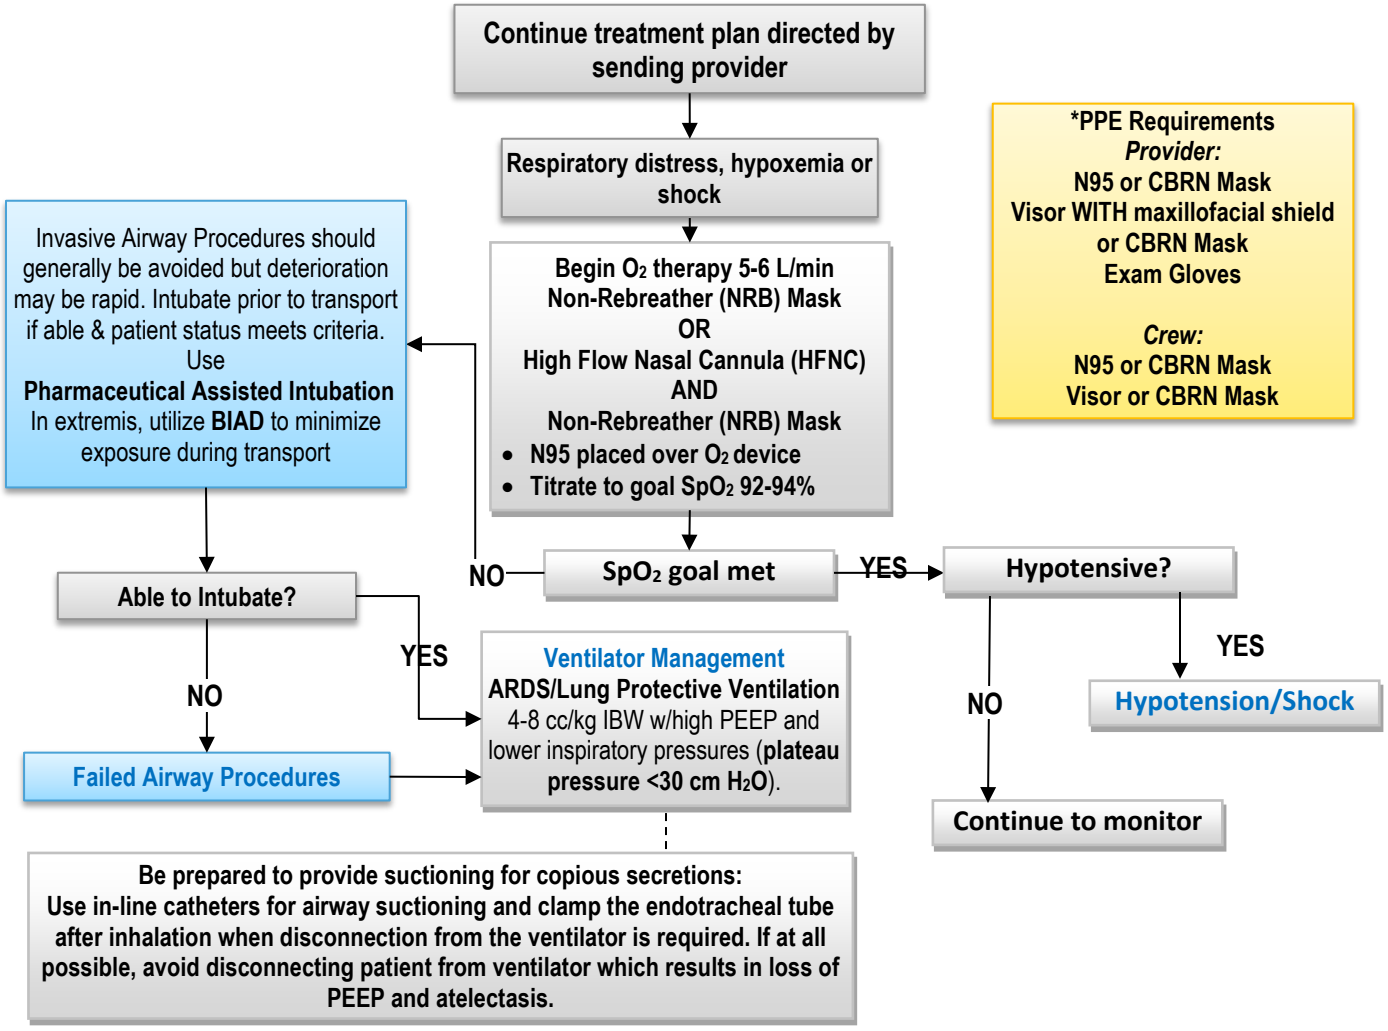
5. With no other alarms occurring, remove external power from the ventilator. The EXTERNAL POWER LOW/DISCONNECT alarms should activate. Reconnect external power to reset alarms. **MAY SKIP THIS STEP IF NOT CONNECTED TO EXTERNAL POWER**

6. If operating using internal battery, verify the Battery Icon indicates sufficient available battery capacity remains to support the anticipated duration of operation.

If either the HIGH AIRWAY PRESSURE, PATIENT DISCONNECT, or EXTERNAL POWER LOW/DISCONNECT alarms fail to activate, continue to manually ventilate the patient, replace the ventilator, and send the unit in for service.

COVID-19 Management

Criteria:
Only as last resort if all ground/fixed wing options have been exhausted. MEDEVAC crews WILL follow OTSG guidance for transport of COVID patients, and transport only if required PPE, PM, decon material and appropriate approval authorities are available BEFORE transport



Continue treatment plan directed by sending provider
Respiratory distress, hypoxemia or shock
Begin O_2 therapy 5-6 L/min
Non-Rebreather (NRB) Mask
OR
High Flow Nasal Cannula (HFNC)
AND
Non-Rebreather (NRB) Mask
N95 placed over O_2 device
Titrate to goal SpO_2 92-94%
SpO_2 goal met
NO
YES
Hypotensive?
YES
Hypotension/Shock
NO
Continue to monitor
Invasive Airway Procedures should generally be avoided but deterioration may be rapid. Intubate prior to transport if able & patient status meets criteria. Use
Pharmaceutical Assisted Intubation
In extremis, utilize BIAD to minimize exposure during transport
Able to Intubate?
YES
NO
Failed Airway Procedures
Ventilator Management
ARDS/Lung Protective Ventilation
4-8 cc/kg IBW w/high PEEP and lower inspiratory pressures (plateau pressure <30 cm H_2O).
*PPE Requirements
Provider:
N95 or CBRN Mask
Visor WITH maxillofacial shield
or CBRN Mask
Exam Gloves
Crew:
N95 or CBRN Mask
Visor or CBRN Mask
Be prepared to provide suctioning for copious secretions:
Use in-line catheters for airway suctioning and clamp the endotracheal tube after inhalation when disconnection from the ventilator is required. If at all possible, avoid disconnecting patient from ventilator which results in loss of PEEP and atelectasis.

Pearls:

- Recognize severe hypoxemic respiratory failure when a patient with respiratory distress is failing to respond to standard oxygen therapy. Prepare to provide advanced oxygen and ventilatory support. Patients may deteriorate rapidly, continuous monitoring is critical!
- Avoid fluids if not in shock. If required, use balanced crystalloids (LR) instead of unbalanced crystalloids (0.9% NS). If patient remains hypotensive, refer to **Hypotension/Shock**
- Do not prone position patients in flight; rehearse for emergency re-proning in event of accidental lost airway
- Favor HFNC over BiPAP/noninvasive ventilation (NIV) if early intubation and mechanical ventilation is not possible.
- Avoid use of nebulized medications, Bag Valve Mask ventilations (BVM), NIV, and suctioning when possible
- Avoid BiPAP if HFNC is unsuccessful and consider early intubation
- Perform continuous EtCO2 monitoring. Permissive hypercapnia is acceptable.
- If high pressure alarms are presenting, it may be necessary to reduce Vt if SpO2 and EtCO2 are within normal limits.
- *Post-mission Decon- Crewmembers should remain in full PPE until completion of mission, not just patient drop-off if aircraft is not being deconned at drop-off site

Epidemiologic risk factors	Exposure category	Recommended Monitoring for COVID-19 *(until 14 days after last potential exposure)*	Work Restrictions for Asymptomatic HCP
Prolonged close contact with a COVID-19 patient who was wearing a facemask (i.e., source control)			
HCP PPE: None	Medium	Active	Exclude from work for 14 days after last exposure
HCP PPE: Not wearing a facemask or respirator	Medium	Active	Exclude from work for 14 days after last exposure
HCP PPE: Not wearing eye protection	Low	Self with delegated supervision	None
HCP PPE: Not wearing gown or gloves[a]	Low	Self with delegated supervision	None
HCP PPE: Wearing all recommended PPE (except wearing a facemask instead of a respirator)	Low	Self with delegated supervision	None
Prolonged close contact with a COVID-19 patient who was not wearing a facemask (i.e., no source control)			
HCP PPE: None	High	Active	Exclude from work for 14 days after last exposure
HCP PPE: Not wearing a facemask or respirator	High	Active	Exclude from work for 14 days after last exposure
HCP PPE: Not wearing eye protection[b]	Medium	Active	Exclude from work for 14 days after last exposure
HCP PPE: Not wearing gown or gloves[a,b]	Low	Self with delegated supervision	None
HCP PPE: Wearing all recommended PPE (except wearing a facemask instead of a respirator)[b]	Low	Self with delegated supervision	None

*****Report all potential high and medium exposures to Flight Surgeon as soon as possible*****

Self-Monitoring with delegated supervision in this setting means HCP perform self-monitoring with oversight by their Flight Surgeon or delegate. On days HCP are scheduled to work, healthcare facilities could consider measuring temperature and assessing symptoms prior to starting work.

Ventilator Exchange Checklist

Two person procedure- One for airway, one for ventilator.

- All persons in the room/area in full PPE
- All equipment gathered and field prepped
- Transport ventilator preset / staged in sequence with circuit- ETCO2- *Filter-Inline Suction
- Temporarily hyper-oxygenate with 100% FiO2 prior to exchange
- Allow patient to inhale
- Clamp tube at end of inhalation (ensure use of smooth clamps or pad ET tube)
- Place primary/in use ventilator in Stand-by (ex. T1) or disconnect inspiratory limb from ventilator side- ensuring to minimize contamination from in-use vent and circuit
- Break the circuit
- Place transport ventilator on patient
- Unclamp ET Tube (ensure tube is open)
- Verify Ventilation

* HME/viral filters should be placed as close to patient as possible and in accordance with manufacturer guidelines

HEMORRHAGE CONTROL PROCEDURES

CLINICAL INDICATIONS:

- Hemorrhage

CONTRAINIDICATIONS:

- None

PROCEDURE:

- Rapid bleeding and/or arterial source recognized (extremities, axial, inguinal) – immediate application of extremity and/or junctional tourniquets, as appropriately needed, to stop bleeding.
- For compressible (external) hemorrhage not amenable to limb tourniquet use Combat Gauze, the CoTCCC hemostatic dressing of choice.
    - Alternative hemostatic adjuncts:
        - Celox Gauze, ChitoGauze, XStat (best for dep, narrow-tract junctional wounds) or iTCLamp (may be used alone or in conjunction with hemostatic dressing or XStat).
    - Hemostatic dressings should be applied with at least 3 minutes of direct pressure (optional for XStat). Must apply adequate force to compress vessels. If size of wound and bleeding are concerning for adequate control, place hemostatic dressing as close to the bleeding vessel as possible followed by 5 min of direct pressure. Each dressing works differently, so if one fails to control bleeding, it may be removed and a fresh dressing of the same type or a different type applied. (Note: XStat is not to be removed in the field, but additional XStat, other hemostatic adjuncts, or trauma dressings may be applied over it.) If bleeding continues, apply a pressure dressing to the wound if applicable.
    - If unable to control bleeding in extremity wounds with above, apply tourniquet. Note: immediate transition to a tourniquet in an extremity wound hemorrhage is preferred.
    - In penetrating injuries to the abdomen, after removing blood, hemostatic dressings should be pushed into the wound and pressure held for five minutes to encourage clotting. Do not remove bandage after placement. Penetrating abdominal/thoracic injuries require a large amount of pressure to compress vessels.

- In pelvic wounds – utilize pelvic binding to limit capacity for hemorrhage (tie pelvis with sheet/commercial binder).
- For external hemorrhage of the head and neck where the wound edges can be easily re-approximated, the iTClamp may be used as a primary option for hemorrhage control. Wounds should be packed with a hemostatic dressing or XStat, if appropriate, prior to iTClamp application. DO NOT APPLY on or near the eye or eyelid (within 1cm of the orbit).
  - The iTClamp does not require additional direct pressure, either when used alone or in combination with other hemostatic adjuncts.
  - If the iTClamp is applied to the neck, perform frequent airway monitoring and evaluate for an expanding hematoma that may compromise the airway. Consider placing a definitive airway if there is evidence of an expanding hematoma.
- Administer IVFs as per guideline – use care with internal bleeding so as not to raise SBP above 80mmHg. MAP should be greater than >60mmHg.
- Consider 2 Grams TXA if significant blood loss.

Document procedure, results, and vital signs.

*****Clear endpoints for fluid resuscitation remain unclear. Resuscitation should be geared towards patient response to therapy. A MAP greater than 60mmHg or a systolic BP between 70-80mmHg is a reasonable goal in trauma patients without a head injury. A MAP between 80-110mmHg or systolic pressure between 110-160mmHg is a recommended goal in patients with a head injury.**

MAP= Mean Arterial Pressure: MAP = [(2 x diastolic BP) + systolic BP] / 3)

Hemorrhage Classification (ATLS)

	Class I	Class II	Class III	Class IV
Estimated Blood Loss (mL)	<750 15%	750-1500 15-30%	1500-2000 30-40%	>2000 >40%
Heart Rate (min)	Normal to slightly elevated	Mild Tachycardia >100-119	Tachycardia 120-140	Tachycardia >140
Respiratory Rate (min)	Normal 12-20	Mild Tachypnea 20-24	Tachypnea 24-40	Tachypnea 24 - >40
Blood Pressure (from baseline)	Normal or slightly elevated	SBP with mild decline	SBP decreased*	SBP decreased (<90mmHg)
Urine Output (mL/hr	Normal > 30	Slight decrease 20-30	Decreased 5-15	Negligible <5
Capillary Refill	1-2 seconds	2 seconds	>2 seconds	> 3 seconds
Mental Status and Skin (color/texture)	Normal or slightly anxious	Mildly anxious, skin may become cool, clammy	Anxious, confused, skin cool, clammy	Confused, lethargic, skin will be cool/cold, pale

TOURNIQUET APPLICATION

CLINICAL INDICATIONS:

- Extremity trauma with continued hemorrhage or amputation.

CONTRAINDICATIONS:

- None

PROCEDURE: All medical personnel should be regularly practiced in deploying and applying all CoTCCC approved tourniquets. Tourniquets should be pre-set and removed from wrapping (ready for immediate use and application).

Initial HASTY placement (over uniform, clearly proximal to bleeding. If site of life-threatening bleeding is not readily apparent, place the tourniquet "high and tight" as proximal as possible on the injured limb.) HASTY tourniquet placement is appropriate for initial treatment of massive hemorrhage or hemorrhage while in care under fire phases. Reassess all HASTY placement tourniquets and asses if hemorrhage is manageable by other methods while in tactical field care or transition to tactical evacuation care. If tourniquet is necessary to manage hemorrhage, replace all HASTY placement tourniquets with DELIBERATE placement tourniquets, preferably prior to patient evacuation, per the following steps:

- Remove clothing as necessary to visualize bleeding area.
- Place tourniquet (commercial or any 2" wide piece of fabric, leather, etc.) directly on skin proximal to wound. Tourniquet should be placed at least 2-3" above bleeding site, proximal or distal to joints, as appropriate.
- Tighten tourniquet by twisting included rod (commercial) or piece of 6" rigid material (e.g., stick) until bleeding stops. If converting from HASTY to DELIBERATE tourniquet placement, loosen HASTY tourniquet. If bleeding is not well controlled with the first tourniquet, apply a second tourniquet side-by-side with the first.
- Secure ends of tension bar to prevent unwinding.
- Document presence of tourniquet and time of placement. ("T" signifies tourniquet). Do not cover tourniquet. Recheck tourniquet intermittently (q 15min) and after any movements to ensure no new bleeding/loosening has occurred.
- **TCCC recommendations:**
    - Limb tourniquets … should be converted to hemostatic or pressure dressings as soon as possible if three criteria are met: the casualty is **not in shock**; it is possible to **monitor the wound closely** for bleeding; and the tourniquet is **not being used to control bleeding from an amputated extremity**. Every effort should be made to convert tourniquets in less than 2 hours if bleeding can be controlled with other means.
    - **Convert all necessary HASTY tourniquets to DELIBERATE tourniquets as soon as tactically feasible.**
    - Do not remove a tourniquet that has been in place more than 6 hours unless close monitoring and lab capability is available.

Document procedure, results, and vital signs.

JUNCTIONAL TOURNIQUET APPLICATION

CLINICAL INDICATIONS:

• High level amputation not amendable to a standard tourniquet, non-compressible hemorrhage in a transition zone (inguinal and axilla), and pelvic immobilization.

CONTRAINDICATIONS:

• None

PROCEDURE: All medical personnel should be proficient in deploying and applying all available tourniquets. Junctional tourniquets (JT) should be pre-set and removed from wrapping (ready for immediate use and application). Junctional tourniquets should be applied according to manufacturer's instructions.

• Remove clothing as necessary to visualize area of application if possible. Remove objects from patient's pockets or pelvic area. Slide device into place as necessary to proper position.

• Tighten tourniquet by twisting or pumping up balloon/bladder until bleeding stops. (depends on JT used)

• Secure all straps in order to ensure security of device.

• Document presence of tourniquet and time of placement on patient (forehead). ("T" signifies tourniquet). Do not cover tourniquet.

• Recheck tourniquet intermittently (q 15min) and after any movements to ensure no new bleeding/loosening has occurred.

• Junctional tourniquets are recommended to be in place for up to **four** hours.

• ***If using a JT with pump device, additional inflation may be necessary with changes in altitude.

• The uniqueness of junctional tourniquets do not lend themselves to conversion well and should be left to Roles with surgical capability. Use caution if attempting Junctional Tourniquet Conversion. Must have high index of suspicion that injury is compressible and can be managed by other adjuncts.

Document procedure, results, and vital signs.

TOURNIQUET CONVERSION

CLINICAL INDICATIONS:

- Wounds that have high possibility of compressible hemorrhage control with hemostatic or pressure dressings where hemorrhage was originally controlled by a tourniquet

CONTRAINDICATIONS:

- Patient showing signs and symptoms of hypotensive/hemorrhagic shock
- Tourniquets controlling hemorrhage for amputated or partial-amputated extremity.
- Tourniquets that have been in place >6 hours.
- Unable to monitor wound for bleeding post tourniquet conversion due to task saturation, limited visibility or poor positioning.

PROCEDURE: Limb tourniquets and junctional tourniquets should be converted to hemostatic or pressure dressings as soon as possible if no above contraindications are present.

Every effort should be made to convert tourniquets in less than 2 hours if bleeding can be controlled with other means. **Do not remove a tourniquet that has been in place more than 6 hours**.

- Confirm patient is not showing any signs of hypotensive/hemorrhagic shock.
- With Tourniquet in place, attempt to pack wound with hemostatic dressing and apply a pressure dressing.
    - Combat Gauze is the CoTCCC hemostatic dressing of choice
    - Alternate hemostatic adjuncts:
        - Celox Gauze
        - ChitoGauze
        - XStat (best for deep, narrow-tract junctional wounds)
        - iTClamp (may be used alone or in conjunction with hemostatic dressing or XStat)
- Loosen but don't remove the tourniquet by unwinding the windlass until pulses return and closely monitor for return of bleeding for 5 minutes.
- If bleeding returns, retighten tourniquet until loss of distal pulse and document procedure failure.
- If no bleeding returns, loosen tourniquet completely but leave loosely looped around limb and monitor for return for bleeding for 5 minutes.
- If bleeding returns, retighten tourniquet until loss of distal pulse and document procedure failure.
- If no bleeding returns, document procedure success and time. Continue to monitor and assess for bleeding.

Document procedure, results, and vital signs.

VASCULAR ACCESS (INTRAVENOUS)

CLINICAL INDICATIONS:

- Need for intravascular access to provide resuscitative fluids and/or medications.
- Anticipated need for intravenous access in emergency patients.

CONTRAINDICATIONS:

- Injuries proximal to IV site/ipsilateral to IV site (relative).

PROCEDURE:

- Prepare all necessary equipment: PPE, tourniquet, IV catheters, alcohol/betadine wipe, saline lock or IV tubing, IVFs if administering, and tape/securing device.
- Ensure all IV tubing/saline locks flushed prior to attempting IV.
- Place venous tourniquet proximal to anticipated IV puncture site.
- Identify vein to be cannulated and cleanse overlying area with alcohol/betadine.
- While holding traction on skin/vessel, cannulate the vessel (use a shallow angle of attack with the needle). Once flash returned, advance slightly to ensure catheter in vessel, then advance catheter only fully into vessel (should pass without resistance).
- While holding pressure proximally on vein and maintaining catheter position, remove tourniquet and needle. Attach NS flush and flush IV – this fluid should flow easily into the vein – any resistance suggests missed attempt or “blown” vein. (Note: If blood samples being drawn – they should be taken prior to removing tourniquet and always prior to flush (after flushing – may obtain dilute sample which will alter results.)
- Secure catheter using transparent dressing or tape.
- Repeat until 2 IV sites have been established and are functional.

Document procedure, results, and vital signs.

VASCULAR ACCESS (INTRAOSSEOUS)

CLINICAL INDICATIONS:

- Need for intravascular access to provide resuscitative fluids and/or medications with inability to obtain adequate peripheral intravascular access (2 failed attempts or greater than 90sec).
- Anticipated need for intravenous access in emergency patients.

CONTRAINDICATIONS:

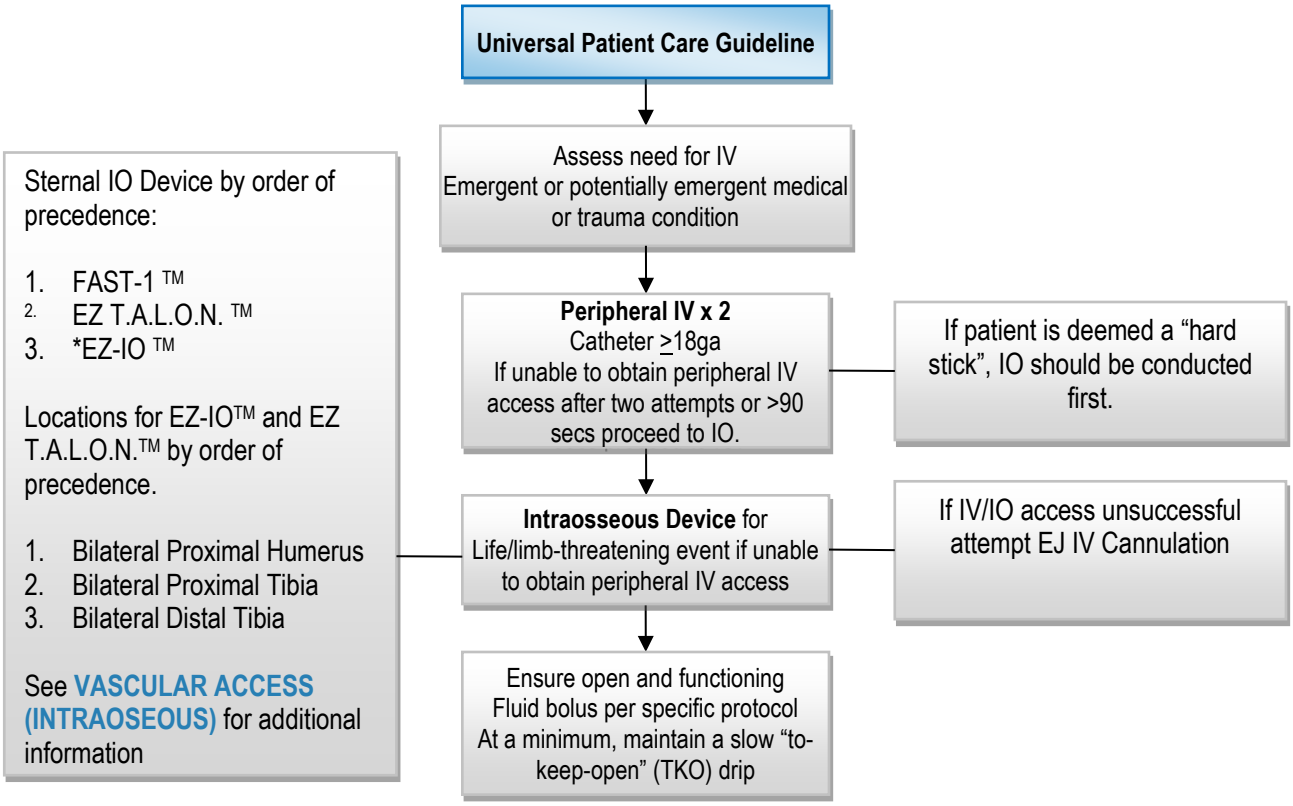
- **Only absolute contraindication is fracture at affected site or prior IO attempt in the same bone.**
- Cellulitis overlying puncture site (relative contraindication).
- Injury (not fracture) proximal to puncture site (relative – site dependent).
- FAST Tactical™ device contraindicated in pediatric patients less than 18 years old.

PROCEDURE:

- Prepare all necessary equipment: PPE, IO device, betadine scrub, and IV tubing.
- Ensure all IV tubing/saline locks flushed prior to attempting IV.
- Identify appropriate puncture area as follows:
  - **FAST Tactical™**
    - **Sternum – follow manufacturer instructions or training guidelines.**
  - **EZ IO™**
    - **Proximal Humerus (YELLOW 45mm) – 1 to 2 cm above the surgical neck into the most prominent aspect of the greater tubercle lateral to intertubercular (bicipital) groove, aiming 45-degrees downward towards contralateral hip.**
    - **Distal Femur (peds, BLUE 25mm) – Proximal to patella (max 1cm) and 1-2cm medial to midline.**
    - **Proximal tibia (BLUE 25mm or PINK 15mm) – 2cm (2 finger widths) distal to tibial tuberosity on medial aspect.**
    - **Distal tibia (BLUE or PINK) – 2cm (2 finger widths) proximal to medial malleolus.**
  - **Manual IO**
    - **Proximal tibia and distal tibia – same as EZ IO™ site.**
- Cleanse site well as failure to appropriately disinfect the area can lead to bone infections.
- Applying firm pressure, puncture skin at 90° angle (45 degree down for Humeral IO), puncture bone (felt as loss of resistance, give or "pop").
- Confirm placement by (1) needle felling firm in bone and (2) aspiration of blood/bone marrow. If unable to aspirate blood, attempt to aspirate after the flush
- Flush IO catheter with normal saline. May add 2% preservative-free Lidocaine without epinephrine to flush to decrease pain (2mL or 40 mg in adults, 0.5mg/kg not to exceed 40mg in pediatric).
- Constantly monitor for increased tension in muscular compartments as misplacement into a compartment with subsequent fluid administration can lead to iatrogenic compartment syndrome.
- With the exception of adult proximal humerus insertions, routinely inserting the needle set to the hub is not recommended technique.

Document procedure, results, and vital signs.

IV / IO PROTOCOL



Universal Patient Care Guideline
Assess need for IV
Emergent or potentially emergent medical or trauma condition
Peripheral IV x 2
Catheter ≥18ga
If unable to obtain peripheral IV access after two attempts or >90 secs proceed to IO.
If patient is deemed a "hard stick", IO should be conducted first.
Intraosseous Device for
Life/limb-threatening event if unable to obtain peripheral IV access
If IV/IO access unsuccessful attempt EJ IV Cannulation
Ensure open and functioning
Fluid bolus per specific protocol
At a minimum, maintain a slow "to-keep-open" (TKO) drip
Sternal IO Device by order of precedence:
1. FAST-1 ™
2. EZ T.A.L.O.N. ™
3. *EZ-IO ™
Locations for EZ-IO™ and EZ T.A.L.O.N.™ by order of precedence.
1. Bilateral Proximal Humerus
2. Bilateral Proximal Tibia
3. Bilateral Distal Tibia
See VASCULAR ACCESS (INTRAOSEOUS) for additional information

Pearls:

- **GAIN VASCULAR ACCESS** where available based upon patient
- Any pre-hospital fluids or medications approved for IV use may be given through an intraosseous line – including blood products.
- All trauma patients or potentially ill patients should have **AT LEAST TWO functioning** IV / IO lines whenever possible.
- Upper extremity IV sites are preferable to lower extremity IV sites.
- Following IV attempt failure and IO attempt failure, external jugular lines can be attempted for life-threatening events with no peripheral access.
- Utilize EZ-IO™, FAST-1™, EZ T.A.L.O.N.™ or unit Medical Director approved IO device.
    - Sternal or humeral head sites are preferred over all other sites.
        - (Tibia is preferred for pediatrics).
    - Correct needle size is critical for the EZ-IO; use of universal/adjustable depth needle or:
        - Yellow - 45mm for humerus and *heavy sternal
        - Blue - 25mm for adult *sternum/tib
        - Pink - 15mm for children and *sternal/tib
    - Pressure infusion bag is recommended for IO starting at 300mmHg

*NOTE: Use of EZ-IO in sternal is off label emergency procedure only see VASCULAR ACCESS (INTRAOSEOUS)

VASCULAR ACCESS via CENTRAL CATHETERS

CLINICAL INDICATIONS:

- In the presence of a life threatening condition, with clear indications for immediate use of medication or fluid bolus. (Not for prophylactic IV access.)

CONTRAINDICATIONS:

- Suspected infection at skin site.

PROCEDURE:

- Determine the type of catheter present: PICC, Broviac, Hickman, Groshong Mediport, etc.

Procedure for peripherally inserted Central Catheter (Cook, Neo-PICC, etc.) and Tunneled Catheter (Broviac, Hickman, Groshong, etc.):

- Prepare equipment:
  - 2 - 3 10 ml prefilled syringes of 0.9% NaCl
  - Sterile gloves (if available)
- If more than one lumen is available (PICCs, Hickmans and Broviacs can have one, two, or three lumens), select the largest lumen available.
- Vigorously cleanse the cap of the lumen with chlorhexidine or 70% alcohol prep pad, allow to dry.
- Unclamp the selected catheter lumen and using a prefilled 10 ml syringe:
  - Vigorously flush the catheter using a pulsating technique and maintaining pressure at the end of the flush to prevent reflux of fluid or blood
  - If catheter does not flush easily (note that a PICC line will generally flush more slowly and with greater resistance than a typical intravenous catheter), re-clamp the selected lumen and attempt to use another lumen (if present)
  - If unable to flush any of the lumens, the catheter is unable to be used
- Attach primed IV administration set and observe for free flow of IV fluid.
  - Utilizing an IV pump, set the flow rate based on the patient condition and IAW SMOG

Document procedure, results, and vital signs.

Procedure for implanted catheter (Port-a-Cath, P.A.S. port, Medi-port):

- Prepare all necessary equipment:
  - Non-coring, right angle needle specific for implanted vascular access ports
  - 2 - 3 10 ml prefilled syringes of 0.9% NaCl
  - Sterile infusion port cap
  - Sterile gloves (if available)
  - Sterile occlusive dressing large enough to completely cover the insertion site
- Identify the access site; usually located in the chest.
- Vigorously cleanse the cap of the lumen with chlorhexidine or 70% alcohol prep pad, allow to dry.
- Attach the infusion port cap to the end of the non-coring, right angle needle tubing.
- Prime the non-coring needle with attached tubing with saline using one of the prefilled 10 ml syringes. Leave the syringe attached to the tubing.
- Palpate the port to determine the size and center of the device.
- Secure the access point port firmly between two fingers and firmly insert the non-coring needle into the port, entering at a direct 90° angle.
- Aspirate 3 – 5 ml of blood with the syringe.
  - If unable to aspirate blood, re-clamp the catheter and do not attempt further use
  - Asking the patient to cough may facilitate access of the port
- Flush the catheter with 3 – 5 ml 0.9% NaCl using a prefilled 10ml syringe.
  - If catheter does not flush easily, do not attempt further use
- Attach IV administration set and observe for free flow of IV fluid.
  - Utilizing an IV pump, set the flow rate based on the patient condition and IAW SMOG
- Cover the needle and insertion site with the sterile occlusive dressing.

Document procedure, results, and vital signs.

CATHETER	SIZE	MAX FLOW RATE
PICC	Less than 2.0 fr	125 mL/hr
PICC	Greater than 2.0 fr	250 mL/hr
Groshong PICC	3 fr	240 mL/hr
Groshong PICC NXT	4 fr	540 mL/hr
Groshong PICC NXT	5 fr	200 mL/hr
Hickman/Broviac	8 – 9.5 fr	3000 mL/hr

PEARLS:

- Do not exceed recommended flow rates.
- Avoid taking a blood pressure reading in the same arm as the PICC.
- Only non-coring, right angle needles specific for implanted ports are to be used for vascular access devices that are implanted in the patient. These are generally not carried MEDEVAC units but may be provided by the patient.
- Priming the tubing of the non-coring needle **is essential** to prevent air embolism.
- There are many peripherally inserted, tunneled and/or implanted ports options. Providers should do their best to discern what option the patient has. Patient may be carrying a reference/wallet card about their device.
- PICC lines will not tolerate rapid infusions or infusions under pressure.

VASCULAR ACCESS via External Jugular Vein Cannulation

CLINICAL INDICATIONS:

- In the presence of a life threatening condition, with clear indications for immediate use of medication, blood or fluid bolus. It should only be used when a peripheral IV site cannot be established (Not for prophylactic IV access.)

CONTRAINDICATIONS:

- Inability to obtain any other suitable peripheral IV access
- Administer IV fluids or blood
- Administer medications

Equipment:

- IV start kit (alcohol swabs 4 x 4s, tourniquet, tape)
- Large bore IV catheter (14 or 16 gauge)
- IV fluid tubing

PROCEDURE:

- Explain the procedure to the patient
- Select the insertion site
- Find the landmarks midway between the angle of the jaw and the midpoint of the clavicle.
- Turn the patient's head away from the intended site of insertion. Consider placing the patient in the Trendelenburg position or holding the thumb over the vein to facilitate insertion.
- Insert the IV catheter pointing towards the ipsilateral acromioclavicular joint until a flash fills the chamber of the catheter, then advance the catheter over the stylet and remove the stylet.
- Attach the IV fluids to the catheter and infuse to verify the intravenous line is patent and dose not infiltrate.
- Secure the IV catheter using tape and a Tegaderm dressing or a clear occlusive dressing.
- Dispose of sharps in an approved biohazard container.
- **Document procedure, results, and vital signs.**

Complications:

- Infiltration
- Hematoma formation
- Cellulitis/infection
- Thrombosis
- Phlebitis

ENROUTE DAMAGE CONTROL RESUSCITATION (DCR)

Indications:

- **Systolic BP <100mmHg**
- **Heart Rate >100 bpm**
- **Hematocrit <32%**
- **pH <7.25**

Injuries associated with need for DCR:

- **Above the knee traumatic amputation (especially if pelvic injury present)**
- **Multi-Amputation**
- **Penetrating injury to chest or abdomen**
- **Intra-abdominal/thoracic hemorrhage**
- **2 regions positive on eFAST scan**
- **Lactate > 2.5**

Continued From: Hypotension Guideline

Trauma Fluid Hierarchy

- Whole Blood (low-titer grp O if available)
- pRBCs, plasma, platelets 1:1:1
- pRBC's, plasma 1:1
- Crystalloid (Plasmalyte-A)

IN THE ABSENCE OF ALL BLOOD PRODUCTS, BEGIN/CONTINUE RESUSCITATION AT STEPS FOLLOWING UTILIZATION OF BLOOD PRODUCT

****THE NEED FOR ONGOING DCR SHOULD BE RELAYED TO RECEIVING FACILITY ASAP TO FACILITATE ACTIVATION OF APPROPRIATE RESOURCES****

Blood Products IAW Trauma Fluid Hierarchy:
Target SBP >100 (>110 TBI)
See Blood Component Therapy Guideline

If No TXA given prior and <3hrs from time of injury/surgery:
TXA 2 Grams / IV/IO / 100ml .09% NS / Bolus or IVP (see drug card)

If 1 Gram TXA given prior and <3hrs from time of injury/surgery:
TXA 1 Gram IV/IO (see drug card)
If >3hrs from time of injury/surgery:

IV Calcium – 30 mL10%Calcium Gluconate
Or **10mL of 10% Calcium Chloride (see pearls)**

If continued decompensation due to uncompressible hemorrhage

Consider 125ml Boluses Plasmalyte A to target MAP > 65 mmHg

Rule out other sources for hypotension (Hemo/Pneumothorax or Tamponade)

Optimize Hypothermia Management:

- **Fluid Warmer**
- **HPMK or Blankets**
- Cabin Heat

Optimize Oxygenation/Ventilation

- **$ETCO_2$-35-45**
- **SpO2 >94%**

At Any Point, Once BP Controlled:

- **Continuous Monitoring**
- **Reassess q 5min**

Return to:
Tactical Evacuation Guideline

Consider (as LAST Resort): Pressors (Preferred)Vasopressin
4 Unit bolus followed by 0.04U/Min to maintain MAP > 65mmHg

Pearls:

- **All patients requiring DCR should be transferred to the closest facility capable of Damage Control Surgery or REBOA ASAP!!!**
- **Blood Product:** Continue to resuscitate with blood product as available and PRN to achieve/maintain target SBP of > 100mmHg (>110mmHg in patients with TBI/Head Injury). If a unit is transfused in a sending hospital the unit must be delivered to the receiving hospital
- **Hypothermia Management:** Blood fluid warmer use and blankets/HPMK/APLS contribute to effective hypothermia management.
- **Calcium**-30ml of 10% Calcium Gluconate or 10ml of 10% Calcium Chloride, given during or after the first unit of blood product and additionally after every 4 units of blood product during continued resuscitation. Calcium Gluconate preferred over Calcium Chloride (if available). Use extreme caution to avoid extravasation.
- **Calcium**-May be given before TXA due to hypocalcemia and blood product use.
- Optimize hemostasis and correct volume loss first!! Avoid the use of pressors or crystalloids unless absolutely necessary to maintain BP in the absence of blood products and ongoing hemorrhage. Hypertonic saline **SHOULD NOT** be used for treatment of hemorrhagic shock.
- **The use of hydroxyethyl starch (Hextend, Hespan) or Factor VII (rhFVIIa) is NO LONGER RECOMMENDED**
- **Administering TXA < 3 hours from time of injury includes both point of injury and post-operative**

BLOOD COMPONENT / FRESH WHOLE BLOOD USE

IMMEDIATE CLINICAL INDICATIONS in trauma patients with SERIOUS INJURIES and evidence of hemorrhage / shock:

- Systolic blood pressure less than 100 mm Hg or absence of radial pulse
- Tachycardia greater than 100 beats per minute (BPM) or higher
- One or more major amputations

CLINICAL INDICATIONS:

- Uncontrolled hemorrhage or evidence of hemorrhagic shock
    - Trauma patients with amputation (complete or partial with distal circulation compromise)
    - Non-compressible penetrating thoracic, abdominal, and transitional zone injuries (axilla, inguinal, neck)
    - Pelvic Fractures in conjunction with traumatic injury (significant mechanism of injury)
    - Clinical signs of coagulopathy
        - Tachycardia, tachypnea, fever, altered mentation, hypoxemia
    - Severe hypothermia associated with blood loss

CONTRAINIDICATIONS:

- None

PRIOR TO BLOOD PRODUCT TRANSFUSION:

- Maximal hemorrhage control
- Treatment of suspected tension pneumothorax
    - Clinical signs may include: hypotension, hypo-perfusion, diminished or absent breath sounds. Late signs include: tracheal deviation and distended neck veins.
- Patent airway or airway control
- IV/IO access
- Hypothermia prevented and/or treated

ORDER OF PRECEDENCE:

- Resuscitate with Whole Blood
- Plasma, RBCs, Platelets in a 1:1:1 Ratio (no particular order)
- Plasma and RBCs in a 1:1 Ratio
- Plasma (thawed, liquid, reconstituted) alone or RBCs alone

PROCEDURE:

- Document all items on the SF 518 (only authorized document for blood products aboard Army Aeromedical Evacuation platforms).
    - Two person verification of patient and blood products given matching SF 518.
- Observe units of blood
    - Look for gas, discoloration, clots, and sediment
    - Safe-T-Vue must remain white on color indicator. Red coloration indicates that temperature has been exceeded and is no longer acceptable for use.
- Initiate large bore IV (18G min, 14G preferred) or IO access.
    - IO access via sternum or humerus is preferred. Tibia site can be utilized as alternate, but attempt should be made to gain another access point.
    - Lidocaine 2% (2-3 mL) flush in IO sites provides analgesia and increases compliance.
- All blood and blood products will be administered through a dedicated line of NS using Y-tubing with filter.
- Transfuse blood through an approved fluid warming device if available.
- Rapid transfusion can be achieved by using an approved pressure infusion device.
    - Inflate pressure bag to at least 300 mmHg
    - 60 ml syringe or manual pressure can also be utilized in the event a pressure infuser is not available.
- Slow all other concurrent infusions unless they are TXA or RFVIIa.
- Resuscitation Goal:
    - until palpable radial pulse, improved mental status or SBP 100 (SBP >110 w/ head injury) and MAP >60 mmHg.
- Addition of Calcium when administering any amount blood will be given. Citrate binding can adversely affect serum Calcium levels. 30 ml of 10% calcium gluconate or 10 ml of 10% calcium chloride IV/IO should be given to patients in hemorrhagic shock during or immediately after transfusion of the first unit of blood product and with ongoing resuscitation after every 4 units of blood products. Ideally, ionized

calcium should be monitored and calcium should be given for ionized calcium less than 1.2mmol/L.

- Monitor patient every 5 minutes and document any patient signs and symptoms consistent with a transfusion reaction. These include: chills, back/chest pain, rash, fever, hives, and/ or wheezing.

Document procedure, results, and vital signs on the SF 518.

CLINICAL PEARLS AND CONSIDERATIONS:

- Febrile Reaction- Temperature increase (1°C or 2°F) from baseline, chills, flushing, headache and rapid pulse
- Allergic/Anaphylaxis Reaction- itching, chills, flushing, nausea/vomiting, coughing and/or wheezing, or laryngeal edema
  - Treat with Diphenhydramine 50mg IVP or IM. Have Epinephrine standing by.
- Acute Hemolytic Reaction- rapid onset of dyspnea, hypotension, hemoglobinuria, rise in venous pressure, distended neck veins, cough and/or crackles at the bases of the lungs. Treatment is to stop the transfusion, titrate O2 saturations above 94%, and increase IV fluid hydration to 100-200mL/hr to support a urine output above 100-200mL/hr.
- Circulatory Overload- onset of shortness of breath, tachycardia, hypertension, jugular vein distention, pulmonary rates, and hypoxia. This condition may be difficult to distinguish from a hemolytic reaction.
- If a casualty with an altered mental status due to suspected TBI has a weak or absent peripheral pulse, resuscitate as necessary to restore and maintain a normal radial pulse. If BP monitoring is available, maintain a target systolic BP goal of at least 110 mmHg.
- Blood is very viscous, use the largest line available to infuse.

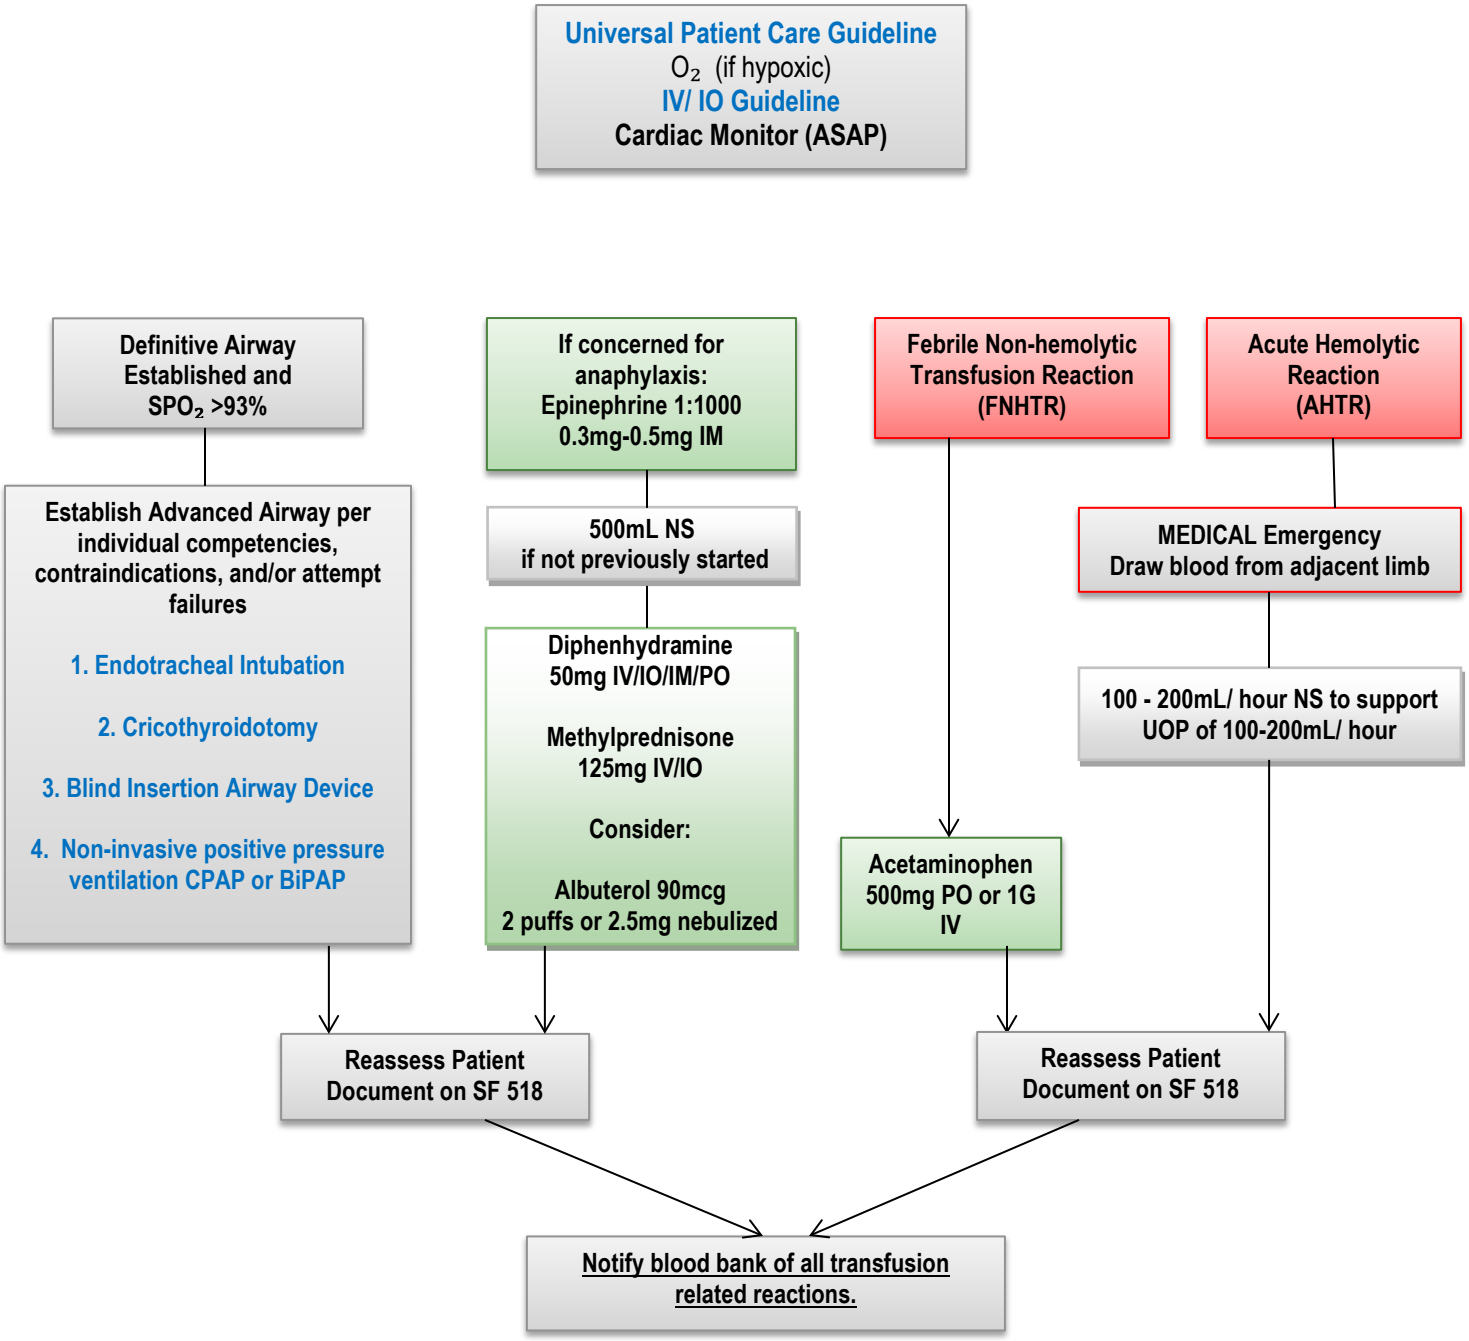
*** Blood component therapy is location specific and is not standard for all missions OCONUS and CONUS.

BLOOD TRANSFUSION RELATED REACTIONS

Differential Diagnosis:	Signs and Symptoms:
Anaphylaxis reaction	Rapid onset of shock, hypotension (<100mmHg systolic), angioedema, and respiratory distress
Acute hemolytic transfusion reaction (AHTR)	Fever (>100.4°F), chills, flank pain, red/brown urine
Febrile non-hemolytic transfusion reaction (FNHTR)	Fever (>100.4°F) or temperature increase of (1°C or 2°F) from baseline, chills, possible dyspnea
Transfusion-related acute lung injury (TRALI)	Hypoxemia (SPO2 <94%), Fever (>100.4°F), hypotension (<100mmHg systolic), cyanosis, tachypnea (>24 breaths per minute), tachycardia (>100 bpm)
Transfusional volume/circulatory overload (TACO)	Dyspnea, orthopnea, tachycardia (>100 bpm), wide pulse pressure, hypertension (>140mmHg systolic), hypoxemia (SPO2 <94%), headache, possible seizure
Mechanical-caused hemolysis	Varies with each device. Fever (>100.4°F), chills, possible dyspnea
Transfusion-transmitted bacterial infection	Fever (>102.2°F or >3.6°F change after transfusion), rigors, tachycardia (>120 bpm or >40 bpm increase following transfusion), rise or fall of systolic blood pressure (>30mmHg)

Pearls:

- GENERAL RULES:
  - Stop the transfusion
  - Keep the intravenous line open with saline
  - Identify and treat cause of the reaction
  - Re-institute the transfusion only if it is deemed to be clinically essential
- Before initiating IVF bolus, ensure IV tubing is new. DO NOT USE existing Y-tubing from blood administration set.
- The most common transfusion reaction is a febrile, non-hemolytic transfusion reaction. These are mostly benign with no lasting sequelae. Treatment consists of antipyretics. (Acetaminophen 500mg PO every 4 hours.)
- TRALI is the leading cause of transfusion-related mortality and commonly occurs is patients who have undergone recent surgery, massive blood transfusion, or who have an active infection. Goal of treatment is supportive and aimed at maintaining oxygenation and reducing respiratory distress.
- TACO is essentially pulmonary edema secondary to congestive heart failure usually occurring in elderly, small children and those with compromised cardiac function. Large volumes of fluid given rapidly are a common precursor to this reaction. Goal is aimed at mobilizing fluids (diuretics) and treating underlying condition. Both TACO and TRALI require immediate resuscitation by an advanced level practitioner.
  - A unit of packed cells should be given at a rate of 2.5-3.0 mL/kg per hour.
- Mechanical-caused hemolysis is commonly caused by rapid transfusion, poor collection and storage, or heating the blood above 42°C during transfusion.



Universal Patient Care Guideline
O_2 (if hypoxic)
IV/ IO Guideline
Cardiac Monitor (ASAP)
Definitive Airway Established and SPO_2 >93%
Establish Advanced Airway per individual competencies, contraindications, and/or attempt failures
1. Endotracheal Intubation
2. Cricothyroidotomy
3. Blind Insertion Airway Device
4. Non-invasive positive pressure ventilation CPAP or BiPAP
If concerned for anaphylaxis: Epinephrine 1:1000 0.3mg-0.5mg IM
500mL NS if not previously started
Diphenhydramine 50mg IV/IO/IM/PO
Methylprednisone 125mg IV/IO
Consider:
Albuterol 90mcg 2 puffs or 2.5mg nebulized
Febrile Non-hemolytic Transfusion Reaction (FNHTR)
Acetaminophen 500mg PO or 1G IV
Acute Hemolytic Reaction (AHTR)
MEDICAL Emergency Draw blood from adjacent limb
100 - 200mL/ hour NS to support UOP of 100-200mL/ hour
Reassess Patient Document on SF 518
Reassess Patient Document on SF 518
Notify blood bank of all transfusion related reactions.

Pearls:

- Blood transfusions conducted during point of injury for casualties suffering from blood loss/massive hemorrhage may not show any transfusion reaction during the limited transport time.

BLOOD GLUCOSE ANALYSIS

CLINICAL INDICATIONS:

- Suspicion of blood glucose abnormalities – hyperglycemia/hypoglycemia.

CONTRAINDICATIONS:

- None

PROCEDURE:

- Gather and prepare equipment.
- Obtain blood samples for analysis as per manufacturer's recommendations.
- Place blood sample onto reagent strip and place into machine for analysis as per manufacturer recommendations.
- Record result and treat any glucose abnormalities per appropriate guideline.
- Perform quality assurance on glucometers weekly. If any suspicious recordings are noted, follow manufacturer's recommendations

Document procedure, results, and vital signs.

Invasive Pressure Monitoring

Purpose:

MEDEVAC Crews are required to monitor invasive pressure on any patient with central venous or arterial access.

Procedure:

- If the referring facility's transducer unit is not compatible with transport unit's cable, replace with compatible transducer setup using aseptic technique.
- Ensure IV pressure bag is preset and inflated to 300mmHg with stopcock closed
- Place transducer at phlebostatic axis and secure with tape
- Zero the line to obtain a "zeroed" reading on the transport monitor
- Flush the line and perform a square waveform test
    - Evaluate the waveform and numeric values for correlation with recent patient trends

Notes:

- Evaluate the insertion site for bleeding, swelling, hematoma, or dislodgement
- Tightly secure stopcocks and cover openings with non-vented endcaps
- Continue monitoring correlation between NIBP and ABP
- Zero the line after movement of patient, at altitude, and if suspected erroneous reading
    - Adjust/re-calibrate monitor every 1000' if required based upon monitoring device
- If waveform dampened, check pressure bag inflation and reassess position of leg/wrist
- If invasive line is in the femoral artery, keep patient head <30° and leg straight. Reassess distal pulses with any patient movement
- Flush line and evaluate square waveform test as needed
- If invasive line becomes dislodged, immediately apply direct pressure

REBOA MANAGEMENT

Purpose:

Surgical Team or SOF Medic placement for trauma arrest or non-compressible hemorrhage in the pelvis. Secondary to emergency thoracotomy or external junctional tourniquets.

Procedure:

- Receive report from team that placed device.
  - Who inserted the device?
  - What type of device (ER-REBOA)?
  - Where located (Zone 1 or Zone 3)? How confirmed? (xray, ultrasound)
  - When was the balloon inflated?
  - Why was it placed (Arrest? Peri-arrest? Pelvic bleed?)
  - How is the device secured?

- Confirm vital sign trends with sending team
- Confirm security of REBOA device with sutures, commercial securing device, or tape.
- Record the length measurement at insertion site.
- Confirm balloon pressure.
- Check distal circulation and any external hemorrhage (Doppler)
- Connect Arterial line to hemodynamic monitoring device.
- Verbalize plan to move patient to next level of care. Ensure time of balloon inflation.
- Continue to closely monitor until patient is secured in the next level of care (Hemodynamic monitoring, distal circulation, device security, catheter depth)

CONCERNS:

- Changes in altitude
- Transient drop in blood pressure
- Change in balloon pressure
- Dislodge of device
- Loss of distal circulation
- Distal external hemorrhage

CARDIAC DEFIBRILLATION

CLINICAL INDICATIONS:

- Patient who is in pulseless cardiac arrest with either ventricular fibrillation or ventricular tachycardia seen on monitor.

CONTRAINDICATIONS:

- None

PROCEDURE:

- Ensure patient attached to monitor / defibrillator. If paddles used, ensure that they are several centimeters away from monitor leads to prevent arcing. Use pediatric paddles as indicated – if unavailable and pads used, should place in anterior / posterior position for pediatric patients.
- Set energy level to appropriate level. Start 200J adult (biphasic) or 360J adult (monophasic), or 2J/kg pediatric.
- Press "charge" button 30 seconds prior to end of compressions. This maneuver minimizes time between compressions and defibrillation. Compressions should continue until end of cycle.
- Ensure all personnel clear of patient and pilots aware of cardioversion.
- Press and hold "shock" button until energy delivered.
- If rhythm converts – treat as per post resuscitation protocol.
- Following shock delivery, immediately begin / return to CPR for 2 minutes before checking for pulse.
- If pediatric patient fails to convert – repeat steps 2-7 above using escalating energy levels.
- **Document procedure, results, and vital signs on run sheet following mission.**

AUTOMATED EXTERNAL DEFIBRILLATOR (AED):

- Turn on power to machine and follow prompts to attach pads to patient and machine.
- Ensure no one touching / moving patient and press the "Analyze" or equivalent button. (If not present, the machine will automatically check the rhythm at dedicated time intervals. A vocal warning will tell you when this is occurring).
- If shock advised, press button to deliver shock and return to CPR for 2 minutes.
- After analysis, if subsequent shocks advised, repeat steps 2-3 up to 3 shocks, until further care arrives, or until no further shock advised. **If no shock advised at any time, CHECK PULSE**. Continue CPR if no pulse. If pulse present, place patient in recovery position and transport.

12-LEAD ELECTROCARDIOGRAM

CLINICAL INDICATIONS:

- Suspicion of arrhythmia.
- Chest pain believed to be of cardiac origin.
- Toxic ingestion with cardiac side effects.

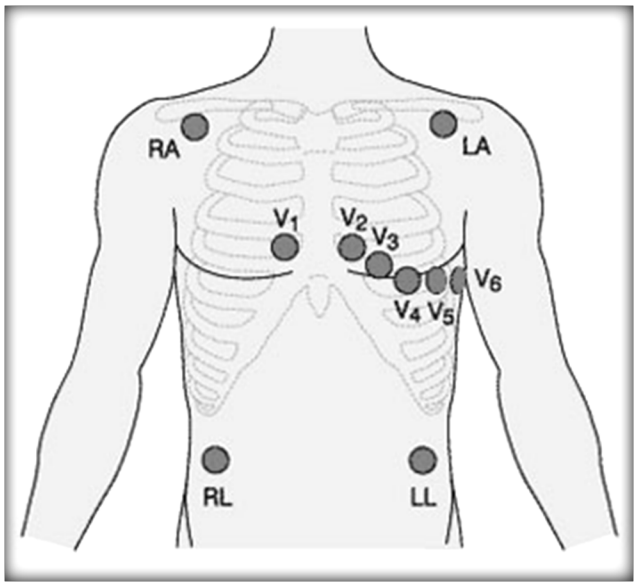
CONTRAINDICATIONS:

- None

PROCEDURE:

- Ensure patient lying flat on bed and place leads as per diagram.
- If patient is unstable, address any emergent issues prior to attempting the 12-lead EKG.
- May have to shave and/or dry patient for pad adhesion.
- Once leads are in place, instruct the patient to remain still and limit any movements around the patient (as possible).
- Press button to obtain 12-lead EKG.
- If questions exist, maintain supportive care and contact medical control if able.

Document procedure, results, and vital signs.



SYNCHRONIZED CARDIOVERSION

CLINICAL INDICATIONS:

- Unstable patient with tachycardia-dysrhythmia noted on monitor/EKG.
- Patient who has failed conservative and/or chemical cardioversion.
- Patient not pulseless.

CONTRAINDICATIONS:

- None

PROCEDURE:

- Ensure patient attached to monitor/defibrillator with synchronized cardioversion capability.
- Time-permitting, ensure adequate IV / IO access present. Ensure that unsynchronized cardioversion/defibrillation capabilities present in case patient degenerates into another dysrhythmia.
- Consider use of sedating medication (e.g., Midazolam 0.1mg/kg (5mg max dose) prior to delivery of shock. **Note: This step is not mandatory and should not delay appropriate management of emergent condition.**
- Set energy level to appropriate level. Usually starting at 50J-100J in adults or 0.5J/kg-1J/kg in children for atrial/ventricular arrhythmias, respectively.
- Select **Synchronized Cardioversion** option. This should result in machine displaying **"SYNC"** as well as tracking electrical activity (arrow or highlighted segment of EKG).
- Ensure all personnel clear of patient and pilots aware of cardioversion.
- Press and hold "Shock" button until energy delivered. (This may take several seconds for machine to synchronize with cardiac cycle. Shock is not immediately delivered as in defibrillation.)
- If rhythm converts – monitor and treat as appropriate.
- If fails to convert – repeat steps 4-7 above using escalating energy levels. If patient degenerates, treat as per appropriate protocol/CPR. **Note: most machines require pushing the "SYNC" after each shock if synchronized cardioversion to be repeated, failure to do so will result in delivery of an unsynchronized shock.**
- **Document procedure, results, and vital signs on run sheet following mission.**

TRANSCUTANEOUS (EXTERNAL) CARDIAC PACING

CLINICAL INDICATIONS:

- Patients with pulse rate <60 (or appropriate for age) and signs of inadequate cerebral or end-organ perfusion.

CONTRAINDICATIONS:

- None

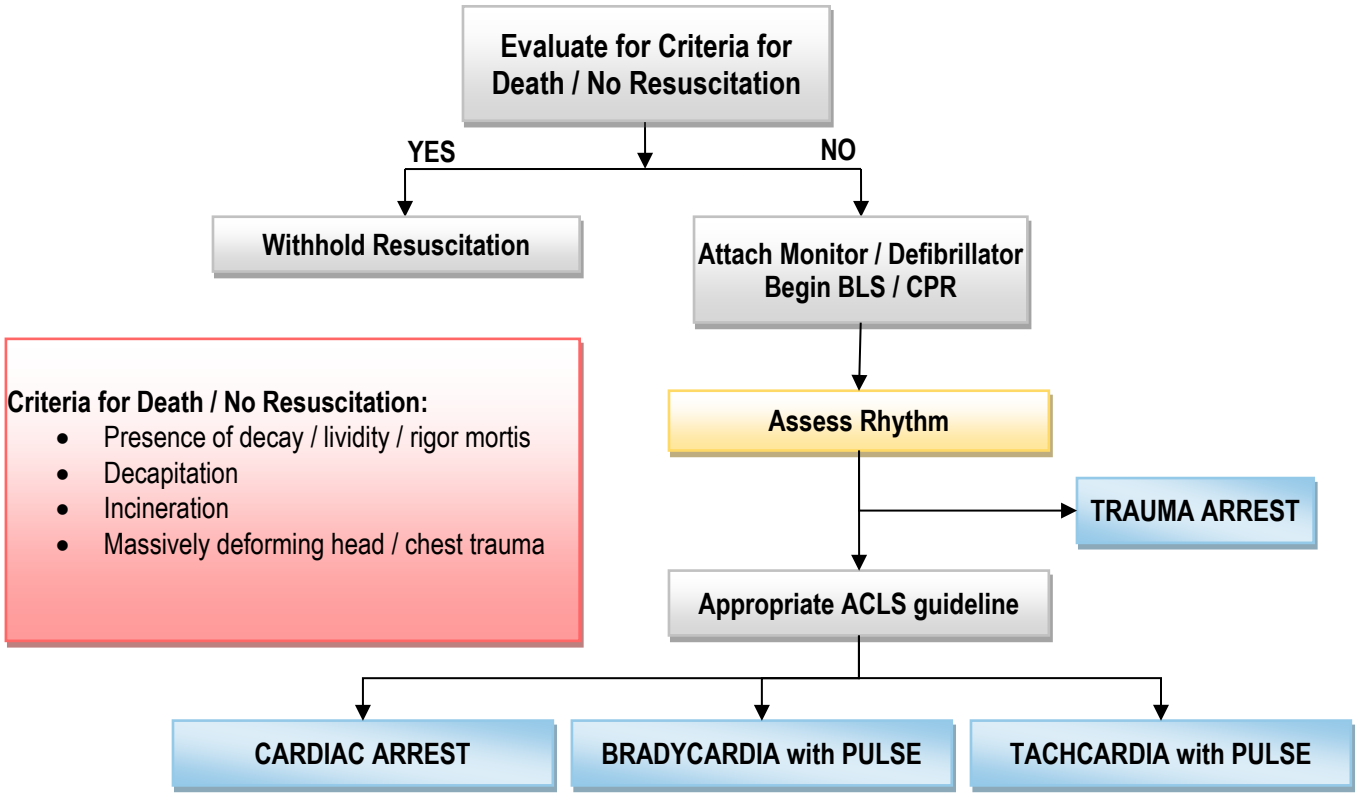
PROCEDURE:

- Ensure patient attached to monitor and defibrillator with external cardiac pacing capabilities.
- Time-permitting, ensure adequate IV/IO access prior to pacing. Also, may administer sedative agent (midazolam) prior to beginning pacing.
- Turn selector switch to "Pace."
- Set rate to twice the patients intrinsic rate (often 70-80 for adult, 100 for pediatric).
- Set energy level to lowest setting and gradually increase until capture is obtained (each pacer spike followed by QRS).
- Once capture obtained, ensure pulse and vital signs correspond with pacing. Evaluate patient for improvement. Monitor and continue sedation as needed.
- If fails to capture at maximal setting, discontinue pacer.
- At any time, if patient degenerates and needs CPR – begin compressions immediately. Pacer pads are insulated and it is okay to perform compressions with pacer running.
- **Document procedure, results, and vital signs on run sheet following mission.**

WITHHOLD RESUSCITATION

Signs and Symptoms:
- **Unresponsive**
- **Apneic**
- **Pulseless**

Differential Diagnosis:
- **Medical vs. Traumatic Arrest**
- **Dysrhythmia**



Pearls:
- As with all ALS protocols – **concentrate on adequate compressions**.
- Minimize interruptions in compressions, including if/when placing advanced airway.
- Early defibrillation associated with greatest success in early cardiac arrest.
- Survival rate for traumatic arrest approaches zero.
- Cardiac arrest in MASCAL situations requires frequent re-triage to apply care where it will be most effective.
- Lack of response alone does not equal death – always check for pulse / cardiac activity.
  - If available, cardiac US can be helpful in determining if continued efforts will be helpful. If there are no signs of cardiac movement on US and there is no other known reversible cause, the likelihood of ROSC and recovery with continued resuscitative efforts in the out-of-hospital setting is incredibly unlikely.

ALTITUDE PHYSIOLOGY AND PATIENT TRANSFER

ALTITUDE CONCERNS FOR AEROMEDICAL TRANSFERS:

- **Gas expansion** occurs as altitude above sea level increases. Gas volume doubles at 18,000' mean sea level (½ sea level atmospheric pressure) and increases 25% from 5,000'-10,000'. This will typically not affect the operational ceiling for the UH-60 Blackhawk during Aeromedical Evacuation operations. Certain conditions and precautions to note:
  - ✓ **Air embolism / Decompression illness** – This is the only absolute contraindication to transport of patients at altitude. These patients should be transferred at sea level or in an A/C capable of cabin pressurization to sea level.
  - ✓ **Pneumothorax** – There is little risk of developing a tension PTX due to gas expansion from altitude during typical aeromedical evacuation flights in rotary-wing A/C. However, altitude should be limited when possible to <5,000' MSL. If mission requirements mandate higher altitudes, the use of aeromedical evacuation platforms with pressurized cabins should be considered as applicable and tactically capable. Prophylactic chest tubes (for altitude-related concerns) are recommended for any flights above 10,000' mean sea level.
  - ✓ **Gastric distention** – Gas expansion does increase the risk of vomiting and, therefore, aspiration. Therefore, all patients with decreased LOC should have an NG / OG tube placed prior to transfer.
  - ✓ **Head injury** – As with PTX, there is little concern of altitude related elevation of elevated ICP in head injured patients although penetrating intracranial or maxillofacial injuries may set conditions for an entrapped-gas phenomenon with adverse clinical consequences. Any evidence of elevated ICP should result in treatment per guideline. Altitude restrictions do not differ from those listed for PTX. Constant vigilance should be maintained for evidence of elevation of ICP.
  - ✓ **Eye injury** – Penetrating eye injuries or surgeries may introduce air into the globe. Again, the altitudes obtained for rotary-wing A/C does not pose a risk of elevating the IOP during normal operations.
  - ✓ **Gas filled equipment** – Medical equipment with gas filled bladders also may suffer from interference at high-altitudes. Primarily, endotracheal tube cuffs and pressure bags which should be evaluated at altitude by testing the pressure of the exterior bladder or filled with air. If able, utilize manometer to

verify tube pressure. A cuff pressure between 20-30 cmH2O is recommended to provide adequate seal and reduce the risk of complications or tissue damage. Verify with supervising physician or flight surgeon before filling endotracheal tube with saline. Routine filling of endotracheal tubes with saline is no longer recommended.

- **Flow Rates:** Decreased atmospheric pressure may interfere with IV flow rates and/or pump function. These must be monitored continuously.
- **Invasive Blood Pressure:** Adjust / re-calibrate monitor every 1000' if required based upon monitoring device.
- **Hypothermia:** As altitude increases, the temperature will drop about 3.5° F per 1000 feet. This is further complicated in the H-60 due to rotor-wash, forward air speed, normal lapse rate. Therefore, patients must be protected from hypothermia at all times. This includes use of the Hypothermia Prevention and Management Kit (HPMK), blankets, heaters if available, and closing cabin doors / crew windows during transport.
- **Hypoxia:** Patients are at increased risk of hypoxia during transport at altitude. If transfers are taking place in high-altitude locations, pulse oxygenation should be monitored at all times and the medic / provider should maintain a low threshold for the use of supplemental O_2. At no time should the patient's O_2 be allowed to go below 92 percent (commercial pulse oximeters read up to 3 percent off, therefore a sat of 91 percent may be seen in a patient who is really at 88 percent.). ***Patients who smoke or have underlying cardiopulmonary disease are at increased risk even at low altitudes.***
- **Dysbarism:** Patients may experience discomfort due to gas expansion in air-filled body spaces (e.g., ears, sinuses, teeth) during ascent. Conversely, patients and aircrew may experience "squeeze" resulting from descent from altitude. These are typically mild during RW transport, however, if severe, altitude should be held and attempts made to alleviate pain and/or slow rate of ascent / descent.

Document procedure, results, and vital signs.

POST-OPERATIVE & CC INTERFACILITY TRANSFER

CLINICAL INDICATIONS:

- Patient at outlying MTF requiring transfer to higher role of care for more definitive surgery/treatment

PRE-TRANSFER Patient Status Requirements:

a. JTS CPG – Intra-theater Transfer and Transport – recommends clinical parameters that should be met prior to transfer; if parameters are not met, they should be addressed and en-route mitigation plans formulated BEFORE departure / transfer:
   1) Heart rate 50><120 bpm
   2) SBP >90 mmHg, MAP >60mmHg
   3) If elevated ICP or CPP, maintain MAP 80><110mmHg, SBP 110><160mmHg
   4) Hematocrit >24% (or Hgb >8g/dL)
   5) Platelet count >50/mm^3
   6) INR <2.0
   7) pH >7.3
   8) Base deficit <5mEq/L
   9) Temperature >35.5^{0}C or 96^{0}F
   10) $ETCO_2$ 35><45, SPO_2 ≥92%, and/or $PaCO_2$ 35><45mmHg

If these criteria are not met, the transferring physician should continue resuscitation or provide documentation indicating limitations that compel urgent transfer. This can be documented in the comments section of the **Standard Order Set for Critical Care Transfers** document.

b. The four *MINIMUM* requirements which will be met prior to patient transfer are hemorrhage control, adequate shock resuscitation (SBP 90 mmHg, MAP >60 mmHg, UOP >0.5 mL/kg/hr, and/or BD <2, Temp >97^{0}F and <100^{0}F), stabilization of fractures, and initial post-operative recovery.
c. Attempt to keep patient packaging time at <25 minutes; use of warming devices in accordance with the JTS Hypothermia Prevention CPG.
d. Movement of Deceased Patients:
   1) In general, patients who meet clinical criteria for death are not to be transported by MEDEVAC, with the exception of extreme extenuating circumstances, such as emergency exfiltration during CSAR.
   2) If vital signs are absent prior to launch, make all reasonable attempts to resuscitate as clinical and tactical circumstances permit. If unsuccessful, consider basic cardiac ultrasound (as available) to determine whether any signs of cardiac activity are present. If absent, mission abort is warranted.

3) In such circumstances, contact and consultation with medical control or other available physician is suggested, in order to facilitate field determination of death and cessation of resuscitative efforts.

PROCEDURE:

a. **Role 2/3 provider responsibilities:**

It is the **responsibility of the transferring physician to write enroute care orders** appropriate for the transport environment and individualized for each patient in consultation with the Critical Care Flight Paramedic and/or the ECCN (or attending Flight Provider) prior to launch. The Flight Paramedic / Provider should be given a **Standard Order Set for Critical Care Transfers** or similar document with en route care orders signed by the transferring physician.

1) Provide a complete report to Flight Paramedic / Provider.
2) Provide all patient-specific related medical records.
3) Assist Flight Paramedic / Provider with packaging patient for transport as requested.
4) Complete specified areas on the appropriate patient care report
   i. Administrative data
   ii. Most current laboratory data
   iii. Mechanism of Injury (MOI)
   iv. Diagnosis
   v. Procedures
5) Place patient on ventilator at least 30 minutes prior to flight. Obtain pre-flight ABG to ensure patient tolerates ventilator settings.
6) It is strongly suggested that the transferring physician make every possible attempt to contact and discuss the case with the receiving physician or facility representative. Flight Paramedics and ECCNs should confirm or encourage this vital "physician-to-physician hand-off" if practicable.

b. **FLIGHT PARAMEDIC / PROVIDER responsibilities prior to transfer**:

1) Obtain orders for en route care from transferring physician; review orders and discuss potential en route problems with transferring physician, reconcile medications (ensure needed medications, specific to patient's condition, are obtained and prepared), allergies and patient's weight, confirm patient's identification, and secure personal effects.
2) Perform primary & secondary assessment ensuring an understanding of the patient's injuries / illness / procedures performed.
3) Spinal immobilization is indicated during transfer if ordered by transferring physician.
4) Assess placement and secure all tubes, lines, and drains & ensure proper functioning.
5) Ensure endotracheal tube is secure; secure pulse oximeter / $ETCO_2$ monitor.

6) Review ABG – ABG should be done within 30 minutes of flight; patient should be on transport ventilator with vent settings for transport; ABG obtained 15 minutes after being placed on transport ventilator.
7) Ensure vascular access X 2 - peripheral, central or IO and A-line as needed.
8) Check all bandages, splints, dressing, fixation devices and tourniquets for placement and ensure no evidence of ongoing hemorrhage.
9) If indicated, insert OG/NG tube for gastric decompression, especially in intubated patients; cap or place to suction.
10) Empty Foley catheter bag prior to flight; ensure UOP documentation by transferring facility.
11) For an intubated patient, provide adequate analgesia and sedation PRIOR to giving additional paralytic medications. Re-dose medications as needed prior to flight in accordance with transferring physician's orders.
12) Continue administration of blood products if ordered by transferring physician. If anticipated administration of blood products enroute, Flight Paramedic/Provider should request orders for blood products and appropriate blood products from the transferring physician and use FDA approved fluid warming device as appropriate for warming fluids.
13) Collect all patient care documentation for transport with patient, i.e. pre-hospital, transport, labs, x-rays, transferring facility notes, etc.
14) Remove all air from IV fluid bags and place all free flowing bags in pressure bags.
15) Ensure patient is properly packaged in a warming device unless contraindicated prior to transfer. Follow directions specific to each warming device ensuring over heating or thermal burns do not occur. Hypothermia, acidosis and coagulopathy constitute the "triad of death" in trauma patients.
16) Securely affix all equipment, supplies, loose tubing and lines to NATO litter prior to moving the patient to the vehicle or aircraft.
17) Once patient is packaged, ensure all lines are leveled and monitors are zeroed.
18) Provide eye and ear protection to patient.

c. Special considerations:

1) Eye Trauma: Fox shields should be placed for any patient with a suspected or confirmed open globe, possible intraocular foreign body or eye injury. **DO NOT remove impaled or stubborn foreign bodies from the eyes.** (even contact lens**) SHIELD AND SHIP. DO NOT PLACE ANY DRESSINGS UNDER RIGID EYE SHIELD** or manipulate the injured eye. Both the injured and uninjured eye should be covered IOT avoid excessive movement of the injured eye which may result from involuntary convergence. Also want to avoid nausea/vomiting in these patients. Normal Saline may be used to rinse eyes in awake patient with no penetrating injury. (JTTS CPG - Initial Care of Ocular & Adnexal Injuries)
2) Compartment Syndrome: Patients with extremity injuries, abdominal injuries/surgery, burns, coagulopathy and those who have received massive transfusion are at risk for compartment syndrome. Ensure proper assessment prior

to flight. If compartment syndrome is suspected during flight, place extremity at the level of the heart. Pain out of proportion to the injury and paresthesia are symptoms of compartment syndrome, as well as pallor, paralysis, pulselessness, and poikilothermia. Patients who are sedated, paralyzed or have an epidural or block in place are at increased risk and require judicious hands on assessment of at risk abdomen and extremities. (JTTS CPG – Compartment Syndrome and Fasciotomy)

3) Burns: For patients with partial and/or full-thickness burns to > 20% TBSA, use of the Burn Patient Admission Orders and **JTTS Burn Resuscitation Flow Sheet** are REQUIRED and should be continued during transfer to another facility. (JTTS CPG – Burn)
4) Advanced pain management modalities: For patients with epidurals, continuous peripheral nerve blocks, PCA infusions, or other pain medicine infusions, a pain note should be completed prior to transport as it is a vital part of provider communication. (JTTS CPG – Management of Pain, Anxiety and Delirium in Injured Warfighters)
5) Sedation and pain management must be maintained at appropriate levels throughout transport. As appropriate and as directed by transferring physician, attempt to maintain sedation target as follows using the Riker Sedation-Agitation Scale (SAS)

Riker Sedation-Agitation Scale (SAS): Used as sedation target goal for Post Surgical / CC

- Non-intubated patients, provide sedation as needed to maintain a goal SAS Score of 3-4.
- Intubated patients, provided sedation as needed to maintain a goal SAS Score of 1-2.

		Definition
7	Dangerous agitation	Pulling at endotracheal tube, trying to remove catheters, climbing over bedrail, striking at staff, thrashing from side-to-side
6	Very agitated	Does not calm despite frequent verbal reminding of limits, requires physical restraints, biting endotracheal tube
5	Agitated	Anxious or physically agitated, attempting to sit up, calms down on verbal instructions
4	Calm, cooperative	Calm, arousals easily, follows commands
3	Sedated	Difficult to arouse, awakens to verbal stimuli or gentle shaking but drifts off again, follows simple commands
2	Very sedated	Arouses to physical stimuli but does not communicate or follow commands, may move spontaneously
1	Unarousable	Minimal or no response to noxious stimuli, does not communicate or follow commands

ECC Nurse Protocols May 2012

d. Patient Care Enroute to the Receiving Hospital

1) Patient vital signs will be monitored continuously enroute and documented at least every 5 – 15 minutes (q5min if on pressors) per transferring physician's orders.
2) Reassess patient at least every 15 minutes and address events as necessary following transferring physician's orders and protocols for the specific illness or injury.

3) Assess pain control, sedation and need for paralysis. Re-dose medications as needed in accordance with transferring physician's orders. Ideally, paralytic medication should not be administered near the end of the flight. Significant, adjunctive analgesia may be required to compensate for initial lift, landing and in flight combat maneuvers, therefore Flight Paramedic/Provider should consider carrying higher volumes of analgesia that would be normally used in ground transport or fixed facilities.
4) All events will be addressed with appropriate interventions according to transferring physician's orders and protocols. All interventions require reassessment for patient response to the intervention.
5) All enroute care, including ventilator changes, medications, events, interventions, and patient's response will be documented on the appropriate patient care documentation.

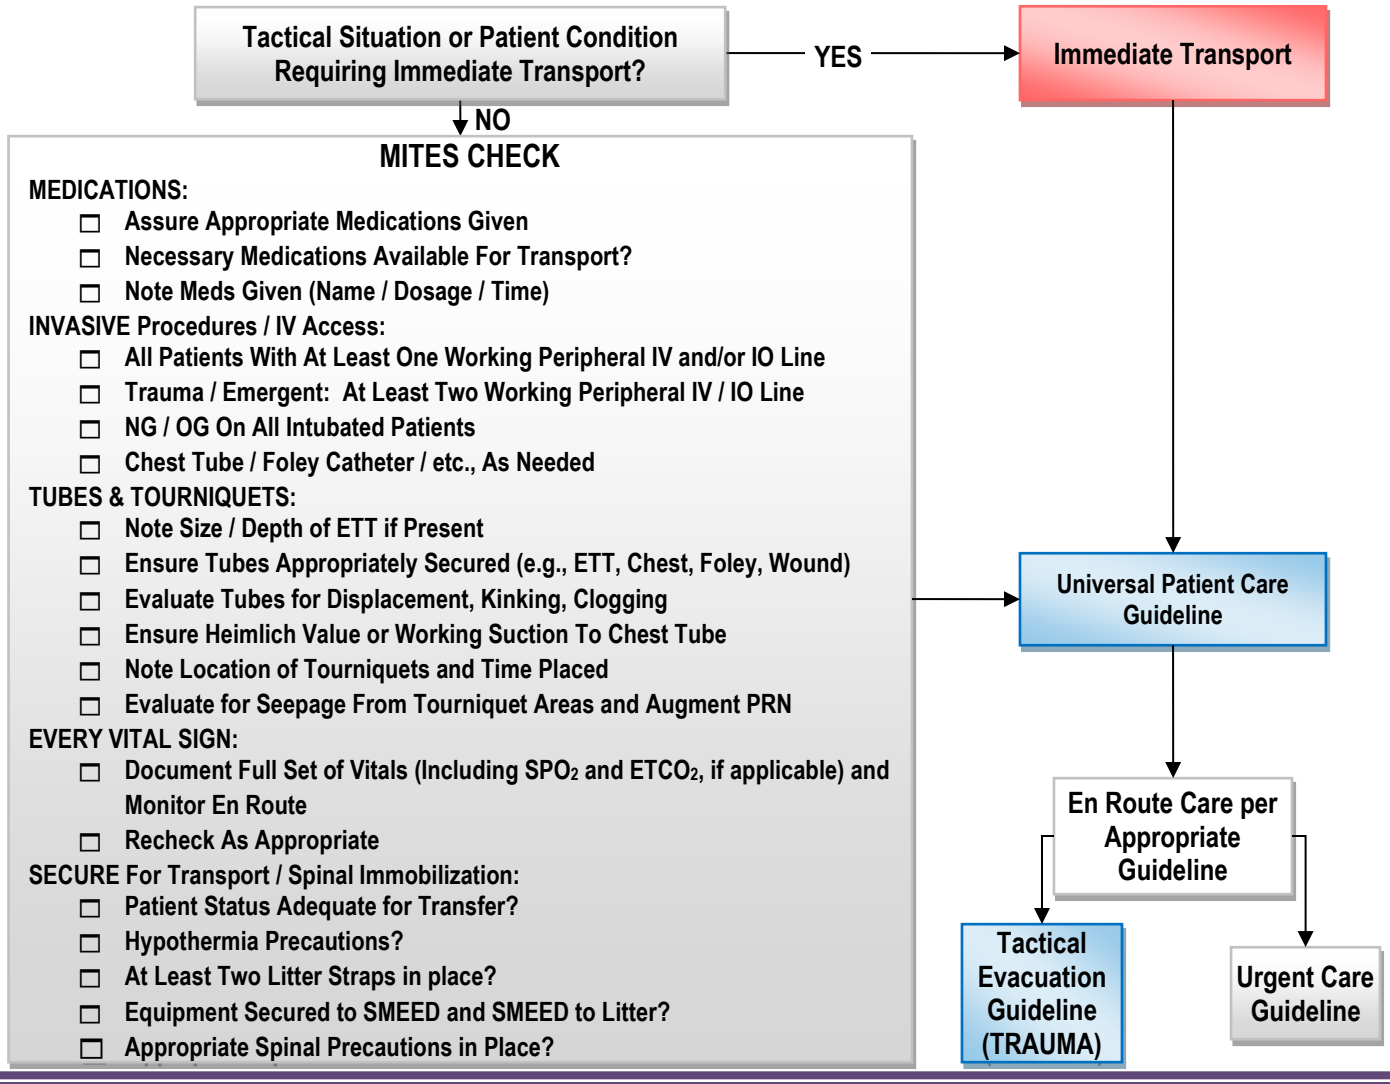
e. Patient Report and Transfer of Care at the Receiving Hospital

1) A verbal and written patient report will be given to the receiving nurse or physician upon delivery of the patient.
2) Routinely, the responsibility of care will be transferred at the receiving ED. On rare occasions (i.e. mass casualty incidents, pending emergency flights, etc.), care may need to be transferred on the helipad rather than at the bedside.
3) For Tail-to-Tail transfers, the Flight Paramedic/Provider initiating transport will send all documentation from the transferring facility and the patient care documentation from the first leg of the flight with the Flight Paramedic/Provider completing the second leg of the transfer. The Flight Paramedic/Provider completing the second leg of the transfer will initiate their own patient care documentation, circling "2nd Leg" at the top of the form and ensure all documentation is turned over to the MTF upon arrival and hand off of patient care.
4) The patient care documentation will be completed and left with the patient at the receiving facility at the time of patient handover. If unable to complete documentation due to extensive mission requirements, the patient care documentation will be forwarded to the appropriate medical information receiving facility/person IAW local / theater policy.

Any in-flight problems should be addressed per appropriate protocol and per written instruction from transferring physician. Continued problems should prompt contacting medical control as soon as it is possible.

Document procedure, results, and vital signs.

PRE-TRANSPORT CHECKLIST



Tactical Situation or Patient Condition Requiring Immediate Transport?
YES
Immediate Transport
NO
MITES CHECK
MEDICATIONS:
☐ Assure Appropriate Medications Given
☐ Necessary Medications Available For Transport?
☐ Note Meds Given (Name / Dosage / Time)
INVASIVE Procedures / IV Access:
☐ All Patients With At Least One Working Peripheral IV and/or IO Line
☐ Trauma / Emergent: At Least Two Working Peripheral IV / IO Line
☐ NG / OG On All Intubated Patients
☐ Chest Tube / Foley Catheter / etc., As Needed
TUBES & TOURNIQUETS:
☐ Note Size / Depth of ETT if Present
☐ Ensure Tubes Appropriately Secured (e.g., ETT, Chest, Foley, Wound)
☐ Evaluate Tubes for Displacement, Kinking, Clogging
☐ Ensure Heimlich Value or Working Suction To Chest Tube
☐ Note Location of Tourniquets and Time Placed
☐ Evaluate for Seepage From Tourniquet Areas and Augment PRN
EVERY VITAL SIGN:
☐ Document Full Set of Vitals (Including SPO2 and ETCO2, if applicable) and Monitor En Route
☐ Recheck As Appropriate
SECURE For Transport / Spinal Immobilization:
☐ Patient Status Adequate for Transfer?
☐ Hypothermia Precautions?
☐ At Least Two Litter Straps in place?
☐ Equipment Secured to SMEED and SMEED to Litter?
☐ Appropriate Spinal Precautions in Place?
Universal Patient Care Guideline
En Route Care per Appropriate Guideline
Tactical Evacuation Guideline (TRAUMA)
Urgent Care Guideline

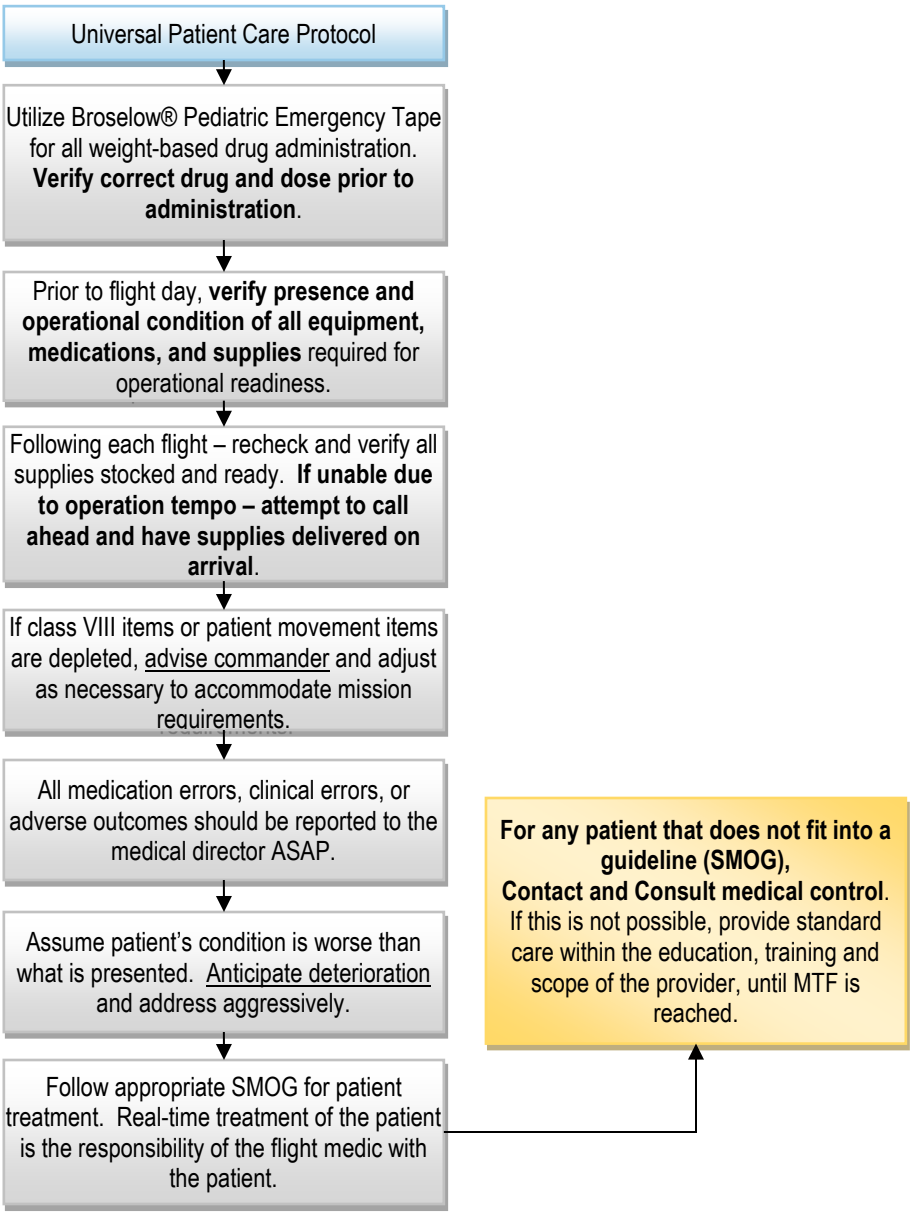
PEARLS:

- Any patient with advanced airway and ventilator support should receive sedation and, if indicated, paralytic agent before flight. These should be available in the aircraft for use by *qualified personnel* for use if patient becomes conscious, agitated, combative, etc.
- Spinal immobilization should be ensured in all blunt trauma (e.g., MVA, fall, blast, combination trauma) where spinal instability may be suspected. The medic should document if spinal injuries are cleared and who cleared them.
- A minimum of two IV / IO sites in patients with emergent or emerging conditions. At least one should be present in all patients transported by MEDEVAC for any other causes. Rare exceptions may exist (e.g., minor musculoskeletal injury).
- All critical care patients should have continuous cardiac monitoring while in en route. This may also extend to non-intubated urgent / priority patients under other circumstances (e.g., acute MI, atypical chest pain).
- **Tactical situation and emergent care should take priority over all other procedures / monitoring.** If unable to perform checks and/or procedures during flight due to the Tactical / Environmental Conditions (e.g., enemy, weather) then this must be documented completely in the Patient Care Report and briefed-back to the receiving medical facility. Continue with monitoring and procedures as soon as situation allows.

DO NOW	TAKE WITH	INFLIGHT
M: ☐ Check all bandages, splints, dressings and tourniquets for placement / evidence of ongoing hemorrhage. ☐ Mark bleeding strikethrough ☐ Measurement of abdomen ☐ Request orders for type and cross-matched blood or O-negative blood from the transferring physician.	**M:** ☐ Additional Blood products (1:1:1) ☐ Tubing ☐ Warmer ☐ Golden Hour Container	**M:** ☐ Blood products administration ☐ Check all bandages, splints, dressings and tourniquets for placement / evidence of ongoing hemorrhage ☐ Measurement of abdomen.
A: ☐ Assess and document ET tube size, depth, security, cuff pressure, bite block ☐ Attach ETCO2 monitor ☐ Insert/Assess and document NG/OG tube placement, size, depth, security ☐ Review chest radiograph for ET confirmation and NG/OG placement ☐ Apply C-collar for airway stability	**A:** ☐ Extra ETT / King LT / IGEL ☐ Suction soft-tip ☐ 10ml syringe ☐ Bite block ☐ Tape ☐ BVM	**A:** ☐ Confirm ETT is in appropriate position ☐ Look/feel for symmetric chest wall rise ☐ Verify tube position at teeth ☐ Check ETCO2 ☐ DOPE
R: ☐ Setup Ventilator and confirm ventilator settings ☐ Check baseline lung compliance/resistance with BVM ☐ Auscultate heart/lung sounds ☐ Check placement and function of chest tube/drainage system/ Heimlich valve. ☐ Request arterial blood gas after transport ventilator is attached to patient	**R:** ☐ O2 for transport ☐ Backup ventilator ☐ Suction ☐ Needle for decompression	**R:** ☐ Look and feel for chest excursion ☐ Check Pulse Ox ☐ Check patient's color
C: ☐ Setup Monitor and zero all Pressure Lines ☐ Assess distal pulses and neurovascular status ☐ Ensure IV access x 2 (Minimum). ☐ Remove air from IV bags and pressurize ☐ IV medications arranged for easy access (20ml, 10ml, 5ml, 3ml) ☐ Review CBC/Chemistry results ☐ Check Foley catheter placement, measure output amount, empty bag	**C:** ☐ Vasoactive medications (dopamine, neo, norepinephrine) ☐ Pressure bags ☐ IV fluids and tubing	**C:** ☐ Check temp, pulse BP, and cardiac rhythm ☐ Assess distal pulses and neurovascular status during transport. ☐ Assess IV access ☐ LZC Pressure Lines
H/I: ☐ Conduct baseline neurologic exam ☐ Provide eye and ear protection to patient; HPMK, warmed IV fluids, blankets and/or chemical heat packs. ☐ Review orders and discuss potential en-route problems with the transferring physician. ☐ Ensure patient and all equipment secured ☐ Place transport ventilator on transport O2 ☐ Assess pain control, sedation and need for paralysis. Re-dose medications if needed before flight ☐ Patient loading considerations	**H/I:** ☐ Collect all labs, x-rays, pre aid-station/hospital documentation for transport ☐ Reconcile medications; verify allergies and patient's weight ☐ Secure personal effects. ☐ Sedation meds (propofol, versed, ketamine) ☐ Pain meds (fentanyl, morphine, ketamine) ☐ Paralytic meds (vecuronium, rocuronium) ☐ 3% NaCl,	**H/I:** ☐ Assess neurologic and sedation ☐ Check placement of all tubes, lines and drains & ensure proper functioning ☐ Ensure all wires and tubing are accessible and have adequate slack to allow monitors and IVs to be properly positioned and secured ☐ Serial assessments ☐ Prepare patient and give report to receiving facility

Altitude Considerations	Medications	Patient Packaging
Required waiting time before transport	Type and number of patients	Additional Medical support/non-medical attendant
Respiratory Support	Monitoring (body systems, medical interventions, etc.)	Telephonic consultation
Equipment	Thermal considerations	Transport time and Route of transfer

PATIENT SAFETY

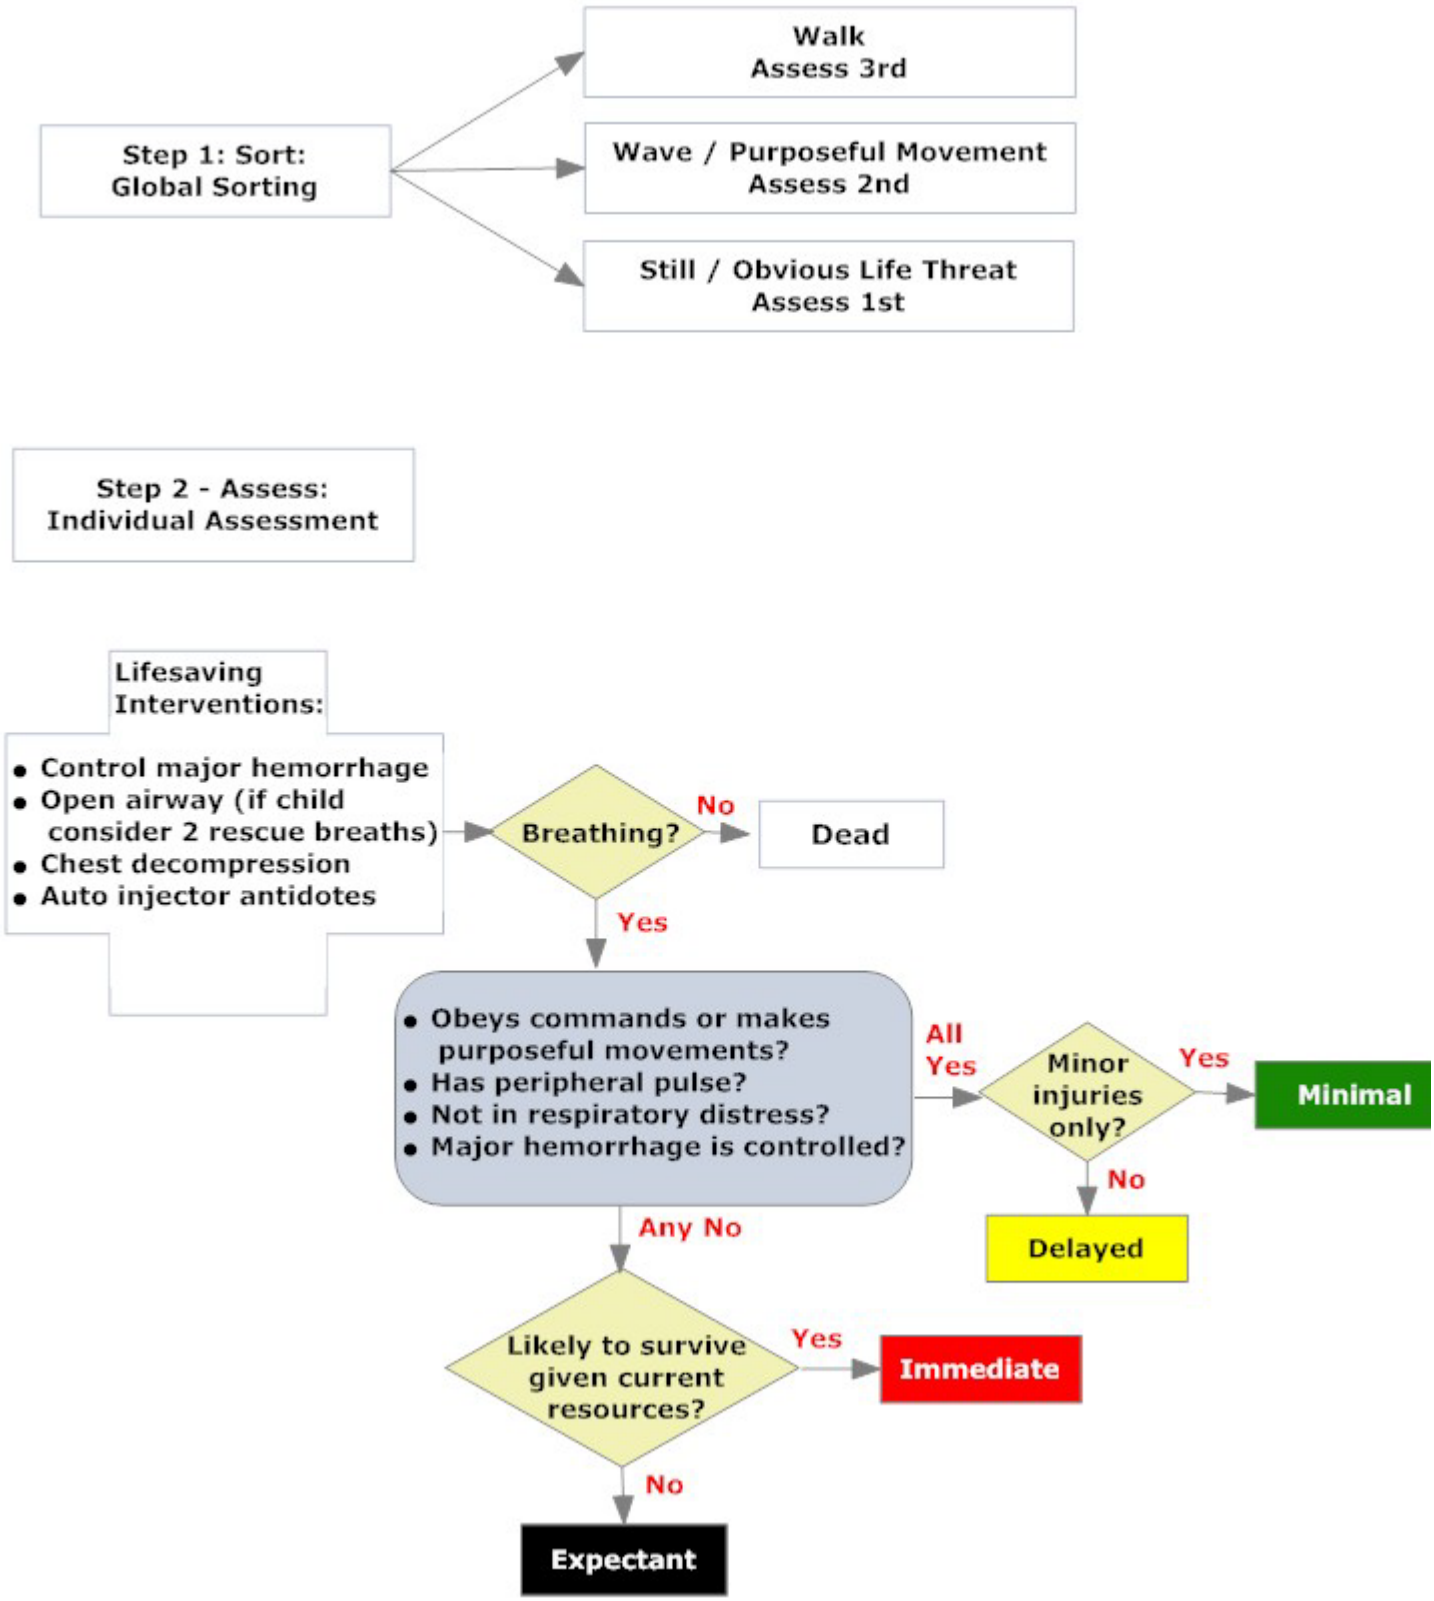


Universal Patient Care Protocol
Utilize Broselow® Pediatric Emergency Tape for all weight-based drug administration. Verify correct drug and dose prior to administration.
Prior to flight day, verify presence and operational condition of all equipment, medications, and supplies required for operational readiness.
Following each flight – recheck and verify all supplies stocked and ready. If unable due to operation tempo – attempt to call ahead and have supplies delivered on arrival.
If class VIII items or patient movement items are depleted, advise commander and adjust as necessary to accommodate mission requirements.
All medication errors, clinical errors, or adverse outcomes should be reported to the medical director ASAP.
Assume patient's condition is worse than what is presented. Anticipate deterioration and address aggressively.
Follow appropriate SMOG for patient treatment. Real-time treatment of the patient is the responsibility of the flight medic with the patient.
For any patient that does not fit into a guideline (SMOG), Contact and Consult medical control. If this is not possible, provide standard care within the education, training and scope of the provider, until MTF is reached.

Pearls:

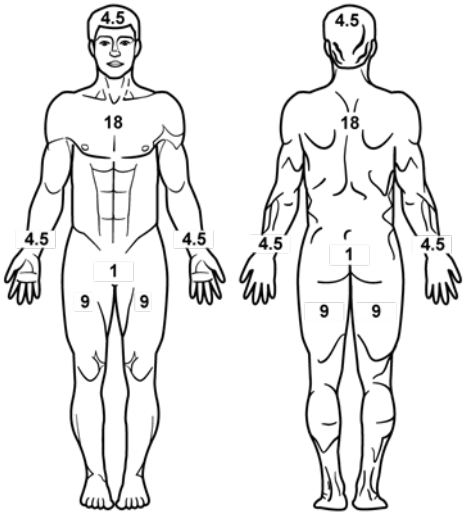
- Supportive care for all patients includes routine monitoring, IV guideline, O_2 / airway support, and fluid resuscitation (as required) to maintain or approach "normal" vital signs.
- Always check and double-check medications, dosage, condition, indication, potential adverse reactions, and control measures prior to administration. Record any patient allergies prior to administration of drugs.
- Check medical supplies and equipment prior to accepting / flying mission. Arrival on scene without proper equipment will result in inability to provide optimal care, and may result in adverse outcomes.
- Any medication / clinical errors or other care-associated concerns should be brought to the attention of the medical officer / director ASAP following the mission or at earliest possible time.

SALT Mass Casualty Triage Algorithm (Sort, Assess, Lifesaving Interventions, Treatment/Transport)



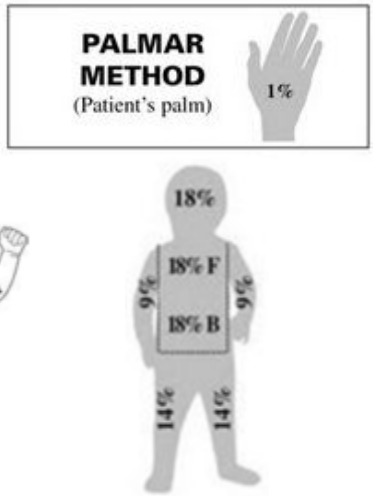
BURN Fluid Resuscitation

Rules of 9 - Burn % Estimation Chart



ADULTS

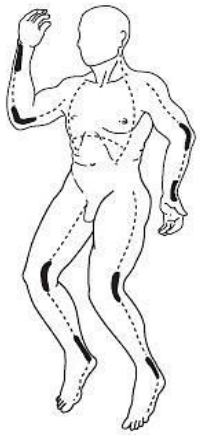
INFANTS



CHILD

Escharotomy-
Dashed line- preferred incision lines.

Bold lines- indicate importance of extending the incision over involved major joints.



Rule of Tens – Fluid Resuscitation Calculations

TBSA > 20%, may require acute fluid resuscitation in prehospital
LR(best)>NS(2nd best)>Hextend(only to 1L)

Adults (>40kg) - **10mL/hr x %TBSA** (estimate to nearest 10%); patients weighing more than 80kg, add 100 ml/hr to IV fluid rate for each 10 kg > 80 kg. Re-evaluate every 1-2 hours. Adjust IV rate to UOP goal 30-50mL (0.5-1 mL/kg in Peds). Adjust IV rate up or down by 20-25%.

Pediatrics (<40kg) - **3 x %TBSA x body weight (kg)** gives the volume for initial 24 hrs. One half is given in first 8 hours. Monitor urine outputwith goal of 0.5 to 1 mL/kg/hr in children.

Example: Pediatric 30kg patient with 50% TBSA 2nd/3rd degree (Chemical or Thermal burn)3mL LR x 50(%TBSA) x 30(kg) = 4,500mL LR in 1st 24hrs
2,250mL (½ of 4,500) is given over 1st 8hrs
2,250mL/8hrs = 281mL/hr for 1st hr, then titrate by 20-25% to UOP goal

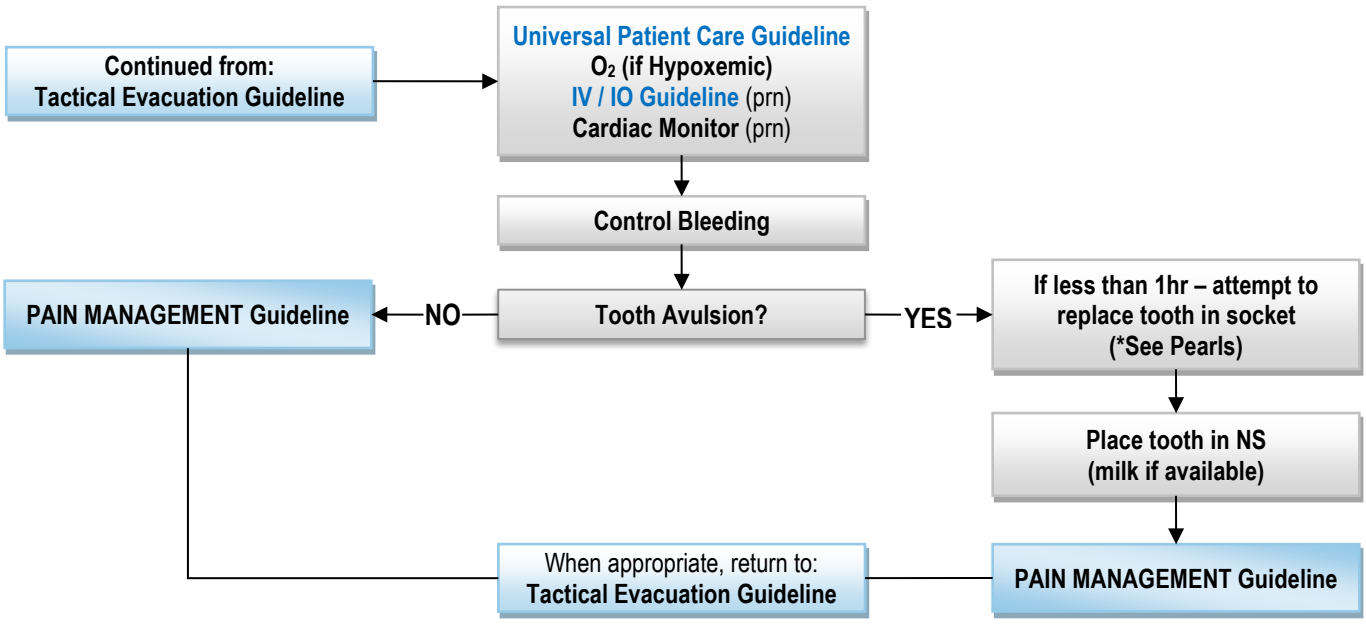
High Voltage Injury: ADULT (>40kg) - 10mL/hr x %TBSA (estimate to nearest 10%); patients weighing more than 80kg, add 100 ml/hr to IV fluid rate for each 10 kg > 80 kg. Re-evaluate every 1-2 hours. Adjust IV rate to UOP goal 75-100mL (1-2 mL/kg in Peds). Adjust IV rate up or down by 20-25%.

Pearls: Both under-resuscitation and over-resuscitation with fluids can precipitate significant adverse clinical eventsfor the burn patient. Thus, it is both worthwhile and imperative that medical aircrew calculate and administer burn resuscitation fluids as accurately and fastidiously as possible. Put another way, it is worth your time and effort to accurately estimate burn surface area, ideal body weight, then calculate and administer appropriate fluids while the patient is under your care.

- Burns with airway involvement require immediate airway protection with Endotracheal Intubation / surgicalairway.
- Burns covering >40% TBSA, will likely require RSI due to airway edema from inflammation/fluid resuscitation.
- **Infants and Young Children should also receive LR with 5% Dextrose at a maintenance rate and monitor for hypoglycemia.**
- Burn patients are prone to hypothermia – must protect from environment. Also, never use ice to cool large burn areas.
- All burns require 100% O2 via NRB unless intubated.
- Never use nitrites for suspected cyanide toxicity in enclosed space fires – can worsen hypoxia. Creates methemoglobinemia. If cyanide toxicity is a tangible threat, consider IV Hydroxycobalmin (CYANOKIT®)

DENTAL PROBLEMS

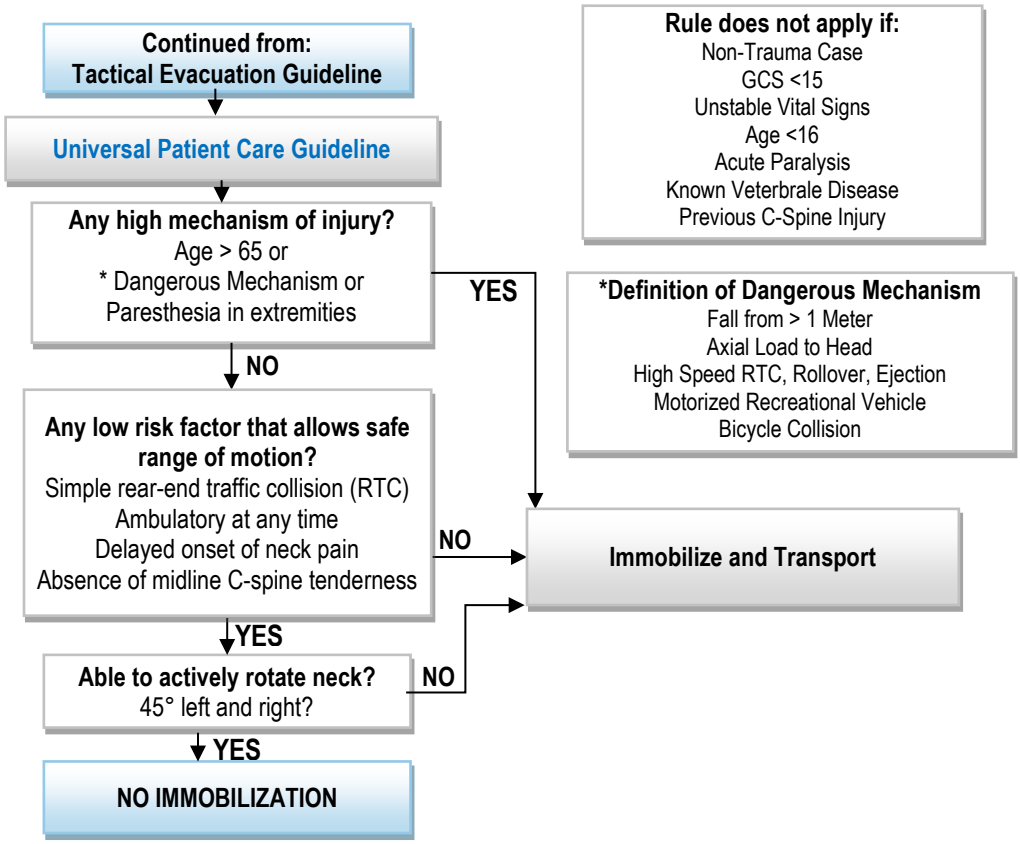
Signs and Symptoms:	Differential Diagnosis:
• **Bleeding**	• **Dental Caries**
• **Pain**	• **Infection**
• **Fever**	• **Fracture**
• **Swelling**	• **Avulsion**
• **Missing / Fractured Tooth**	• **Abscess / Cellulitis**
	• **Gingivitis**



Pearls:

- Significant soft tissue swelling to face / mouth can represent cellulitis or an abscess.
- **Avulsion** (Complete Avulsion Only)
  - Gently rinse (do not scrub) tooth with NS and attempt to re-implant with firm pressure into the socket. **Never perform this in children with primary teeth**.
  - As able and without obstructing airway, place bulky dressing over tooth and use as a soft bite block to stabilize tooth. Instruct to bite down gently, do not move jaw.
- **Subluxation** (tooth displaced in socket)
  - Treatment not always required.
  - For obviously loose or displaced tooth consider placing bulky dressing over tooth and use as a soft bite block to stabilize tooth. Instruct to bite down gently, do not move jaw.
- Occasionally, cardiac chest pain can radiate to the jaw.
- Patient with dental abscess may experience significant pain at altitude due to gas volume expansion at lower atmospheric pressure. Consider flying at lower altitude and refer to pain management guideline.

SPINAL EVALUATION & IMMOBILIZATION/CANADIAN C-SPINE RULE (CCR)



CONTRAINDICATIONS:

- Patients with isolated penetrating cervical injury who are conscious and have no neurologic signs should not have a cervical collar placed in the pre-hospital environment.

PROCEDURE:

- Evaluation should take place after the primary survey and all emergent procedures completed. However, during the primary survey, the spine should be protected by manual inline stabilization / limited movement prior to completion of spinal examination. This does not apply to situations in which imminent danger exists and immediate movement is necessary.

Document procedure, results, and vital signs.

- On the battlefield, safety of patient and medical personnel are paramount. In hostile situations, evacuation to a more secure area takes precedence over spine immobilization.

FOLEY CATHETER PLACEMENT

CLINICAL INDICATIONS:

- Bladder distention in an unconscious person, or for blockage / inability to urinate in conscious person.
- Allows for accurate monitoring of output for fluid management.

CONTRAINDICATIONS:

- Known or suspected urethral disruption resulting from pelvic trauma.
- Combative or uncooperative patient.

PROCEDURE:

- Choose appropriate catheter (16-18 for adults) and ready equipment.
- Position patient. Females in supine position with legs abducted. Cleanse urethra and surrounding area with antiseptic solution. Isolate area with drapes provided.
- Insert xylocaine jelly provided into urethra with the syringe provided.
- Insert catheter into urethra. For **females** advance the catheter approx. 3 inches. For **males**, pass catheter into the bladder the full length to the junction of the catheter and inflation port for balloon.
- Once urine is obtained, inflate balloon with 5cc NS, then pull catheter outward until balloon against bladder neck. If no urine return is given and procedures to induce urine return (bladder palpation) do not work, DO NOT inflate the balloon.
- Secure catheter to leg with tape to prevent trauma to urethra. Document procedure.

Document procedure, results, and vital signs.

NASO / OROGASTRIC TUBE

CLINICAL INDICATIONS:

- Enabling gastric decompression, decreasing risk of vomiting and aspiration, obtain sample of gastric contents.
- Allows for gastric lavage in drug overdose or poisoning.

CONTRAINDICATIONS:

- Nasogastric tubes contraindicated in the presence of massive facial trauma, burns, or suspicion of basilar skull fracture (CSF otorrhea, Battle's sign, raccoon eyes, mechanism). May insert orogastric tube instead.

PROCEDURE:

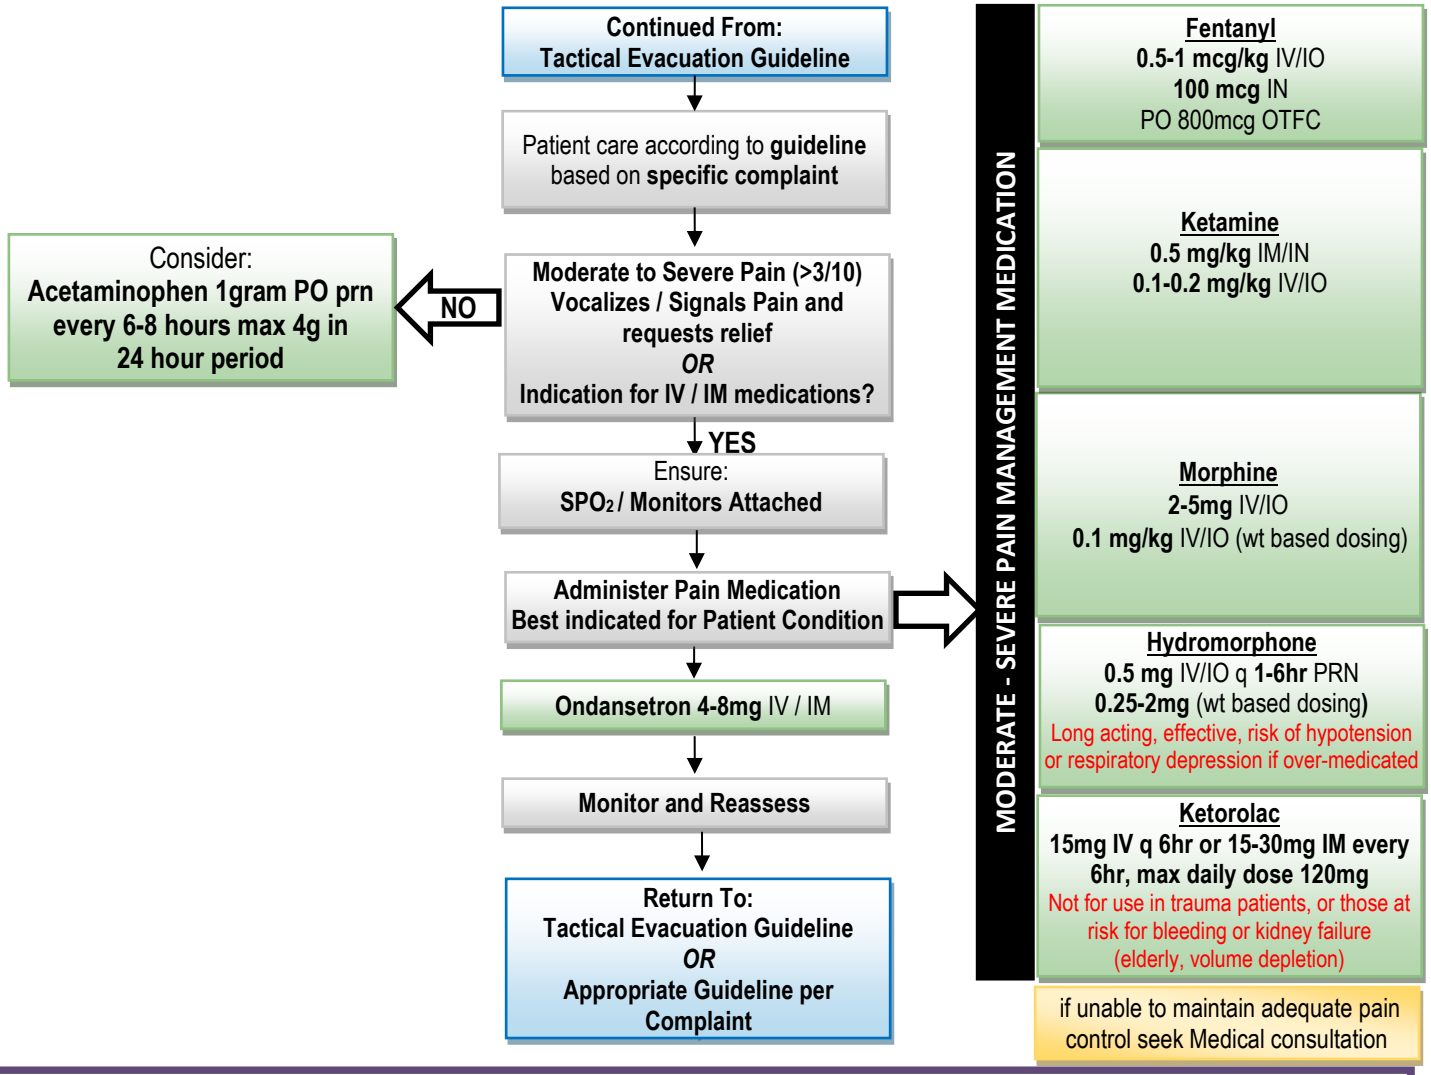
- If possible, sit patient upright for optimal neck and stomach alignment.
- Measure tubing from bridge of nose to earlobe, then to the point halfway between the end of the sternum and the navel. Mark measured tube with marker.
- Select most patent nare (or the throat) and pass lubricated tube in a posterior – NOT SUPERIOR – direction. If resistance is met, attempt to corkscrew slightly or remove and attempt in other nare.
- Withdraw tube immediately if changes occur in patient's respiratory status, if tube coils in mouth, if the patient begins to cough, or becomes cyanotic.
- Advance tube until mark is reached.
- Verify tube placement by listening over stomach while air is passed or examining aspirate when applied to suction. Secure tube. Watch vital sign for changes.

Document procedure, results, and vital signs.

PAIN MANAGEMENT

Signs and Symptoms:

- **Tachycardia**
- **Diaphoresis**
- **Elevated Blood Pressure**
- **Vocalizes and/or Signals Pain**



Continued From:
Tactical Evacuation Guideline
Patient care according to guideline based on specific complaint
Moderate to Severe Pain (>3/10)
Vocalizes / Signals Pain and requests relief
OR
Indication for IV / IM medications?
NO
Consider:
Acetaminophen 1gram PO prn every 6-8 hours max 4g in 24 hour period
YES
Ensure:
SPO2 / Monitors Attached
Administer Pain Medication
Best indicated for Patient Condition
Ondansetron 4-8mg IV / IM
Monitor and Reassess
Return To:
Tactical Evacuation Guideline
OR
Appropriate Guideline per Complaint
MODERATE - SEVERE PAIN MANAGEMENT MEDICATION
Fentanyl
0.5-1 mcg/kg IV/IO
100 mcg IN
PO 800mcg OTFC
Ketamine
0.5 mg/kg IM/IN
0.1-0.2 mg/kg IV/IO
Morphine
2-5mg IV/IO
0.1 mg/kg IV/IO (wt based dosing)
Hydromorphone
0.5 mg IV/IO q 1-6hr PRN
0.25-2mg (wt based dosing)
Long acting, effective, risk of hypotension or respiratory depression if over-medicated
Ketorolac
15mg IV q 6hr or 15-30mg IM every 6hr, max daily dose 120mg
Not for use in trauma patients, or those at risk for bleeding or kidney failure (elderly, volume depletion)
if unable to maintain adequate pain control seek Medical consultation

Pearls:

- Document patient's medications and all allergies prior to administration of medications.
- PO medications should not be used in any patient with altered mental status or anyone in whom surgery is anticipated, unless directed by transferring provider.
- **Narcotic pain medications can be reversed with Naloxone 0.4-2mg IV.**
- Start with low dosage of pain medications and titrate upward to desired effect.
- Fentanyl and Morphine will cause a decrease in BP through various drug effects. Fentanyl is preferred over Morphine for immediate pain control.
- **Treatment of "Ketamine Associated Psychiatric Distress" or "Ketamine induced agitation,"**
  - **Midazolam 2-5mg IV x1 prn for agitation due to Ketamine administration**
- Morphine and/or Ketamine auto-injectors may be used if available; however IV / IO route is preferred.
- Ketamine can cause slight decrease in blood pressure, especially with hypotensive shock patients, lower doses are recommended in this type of patient.
- Fentanyl OTFC 800mcg may be used if patient is conscious. Do NOT CHEW

Pediatric PAIN MANAGEMENT
Vital Functions and Pain Scale

Signs and Symptoms:
- **Tachycardia, Diaphoresis, Elevated Blood Pressure, Cry, Grimace, Splinting, Guarding**

AVERAGE PEDIATRIC VITAL FUNCTIONS

HEART RATE	107-181	93-161		88-156	70-142	59-131		52-115		43-108
RESP RATE	25-66	22-64		19-53	17-38	16-29		14-25		12-23
SYSTOLIC BP	60	79-105		85-108		88-110	91-119		97-137	
DIASTOLIC BP		34-81		40-69		45-68	51-89		59-86	
URINE (mL/kg/hr)	2			1.5		1			0.5	

Weights and lengths in above chart are estimates, to achieve most accuracy utilize Broselow tape on patient

Pediatric FLACC Pain Scale

(2 Months – 7 Years or Individuals Unable to Communicate)

Score of 5-10 = Moderate-Severe Pain, Consider Narcotic

Criteria	0	1	2
Face	No particular expression or smile	Occasional grimace or frown, withdrawn, uninterested	Frequent to constant quivering chin, clenched jaw
Legs	Normal position or relaxed	Uneasy, restless, tense	Kicking or legs drawn up
Activity	Lying quietly, normal position, moves easily	Squirming, shifting, back and forth, tense	Arched, rigid or jerking
Cry	No cry (awake or asleep)	Moans or whimpers; occasional complaint	Crying steadily, screams or sobs, frequent complaints
Consolability	Content, relaxed	Reassured by occasional touching, hugging or being talked to, distractible	Difficult to console or comfort

In hemodynamically unstable or inconsolable child, consider:

Ketamine

(IV / IO Push over 1 min)
- Analgesia:
  IM / IN: 0.4 mg/kg
  IV / IO: 0.3 mg/kg
- Induction / Dissociative:
  IV / IO: 1-2 mg/kg

FENTANYL 0.5-2mcg/kg SIVP
q 20-30min (Max 4mcg/kg)

MORPHINE 0.1mg/kg IV SIVP/IM
q 120min (Max 0.4mg/kg)

Follow Procedural steps of:
PAIN MANAGEMENT GUIDELINE
Utilize Appropriate Medication in Pediatric Dose.

Acetaminophen 10-15mg/kg PO / PR

ONDANSETRON (for Nausea)
- **≤40kg 0.1mg/kg IV**
- **>40kg 4mg IV**

HYPOTHERMIA PREVENTION AND MANAGEMENT

CLINICAL BACKGROUND:

- Hypothermia, acidosis, and coagulopathy constitute the "triad of death" in trauma patients. The association of hypothermic coagulopathy with increased mortality has been well described. Over 80% of non-surviving patients have had a body temperature of less than 93.2°F(34°C). This degree of hypothermia causes dysfunction of coagulation proteins, thus exacerbating hemorrhage. The mortality in combat casualties with hypothermia is double that of normothermic casualties with similar injuries.
- Prevention of hypothermia must be emphasized in combat operations and casualty management at all levels of care. Take early and aggressive steps to prevent further body heat loss and add external heat when possible for both trauma and severely burned casualties.
- Hypothermia occurs regardless of the ambient temperature; hypothermia can, and does, occur in both hot and cold climates.
- Prevention of hypothermia is much easier than treatment of hypothermia; therefore prevention of heat loss should start as soon as possible after the injury. This is optimally accomplished in a layered fashion with rugged, lightweight, durable products that are utilized at all subsequent levels of care, including ground and air evacuation, through all levels of care.

CONTRAINDICATIONS:

- Hyperthermia patients that require active cooling

PROCEDURE: Tactical Combat Casualty Care principles should be followed for preventing hypothermia.

- Primary Equipment
    - Hypothermia Prevention and Management Kits (HPMK). HPMK contains:
        - strong, flexible, lightweight Heat Reflective Shell that is impervious to wind & rain
        - Hood cover for Head
        - self-heating, oxygen-activated shell liner (ReadyHeat)
    - Blood Fluid Warmers
    - ReadyHeat Blankets
    - Wool or heat shield blankets

Take aggressive action to prevent hypothermia and maintain normothermic temperatures 97°-99° F (36°- 38° C)

- **Blood/Fluid Warmers:** Utilize blood/fluid warmers for all IV/IO administration. Fluids should be warmed to 38° Celsius.

- **Head Cover:** Cover patients head with hood or Thermo-Lite Hypothermia Prevention System Cap. Greatest area of heat loss happens at the top of the patients head.

- **ReadyHeat Blankets:** Place the ReadyHeat Blanket on the torso and back of the casualty with a layer of clothing or a sheet or wool blanket between the casualty's skin and the Ready-Heat Blanket.
- **Cover Patient:** Utilize Heat Reflective Shell, rescue or wool blankets to cover the patient. Use blankets to insulate patient from cold surfaces.
- **Remove Wet Clothing:** Remove wet clothing and attempt to dry patient.
- **Close doors and windows:** Reduce heat loss from convection over the patient and cooling of the environment.
- **Cabin Auxiliary Heater:** Even on mildly warm days, use cabin aux heat to maintain treatment area temperature of >85° – 90° Fit
- **Limit Exposure**: only expose areas necessary to visualize and work on the patient. Cover exposed areas as soon as able following procedures.

Continuously monitor patient and record temperature. A core temperature should be taken for best accuracy.

Document procedure, results, and vital signs.

***Troponin assays are becoming more analytically sensitive. Each device has different reference ranges associated. Correlate cTn with reference lab. Point of care readers are less sensitive.**

USEFUL CALCULATIONS

PEDIATRIC FORMULAS:

- **ETT Size = (**Age/4)+4 (Age divided by 4 plus 4)
- **ETT Depth =** 3 x ETT Size (Endotracheal)
- **Weight in kg** (>1 year) = (Age (years) x 2) + 8
- **Systolic Blood Pressure minimum** = 70 + [2 x Age (years)]

MEDICATION FORMULAS:

- **Mcg/kg/min (micrograms/kilogram/minute)** = [16.7 X Drug Concentration (mg/ml) x infusion rate (ml/h)] Weight (kg).
- **INFUSION RATE (ml/h)** = [Desired mcg/kg/min x Weight (kg) x 60]/Drug concentration (mcg/mL)

HEMODYNAMIC FORMULAS:

- **MAP**: Mean Arterial Pressure = [(2 x DBP) + SBP]/3.
- **SBP** = (Systolic Blood Pressure)
- **DBP** = (Diastolic Blood pressure)
- / = (Divided by)
- **PULSE PRESSURE:** SBP – DBP or (Systolic Blood Pressure minus Diastolic Blood pressure).
- **Cerebral Profusion Pressure (CPP):** MAP-ICP=CPP
- **ICP**= (Intracranial Pressure)
- **Ideal CPP=>65** While ICP cannot often be measured during flights; an assumption that patients with TBI have an ICP of 15-20 will allow hemodynamic optimization in these patients to ensure adequate CPP.

Common Conversions:

- lbs. = kg x 2.2 or kg = lbs. x 0.45
- Fahrenheit = (Celsius x 1.8) + 32 or Celsius = (Fahrenheit -32) x 5/9
- 1 tsp. = 5 ml
- 1 tbsp. = 15 ml
- 1 oz. = 30 ml
- 1g = 1,000 mg
- 1mg = 1,000 mcg
- 1 g = 10,000 mcg

OXYGEN CYLINDER LIFE:

Cylinder	D	E	G	H
Liters	**356**	622	5260	6900
Flow (LPM)	**Length of use (min)**	**Length of use (min)**	**Length of use (min)**	**Length of use (min)**
2	**178**	311	2630	3450
4	**89**	155	1315	1725
6	**59**	104	876	1150
8	**44**	78	658	862
10	**35**	62	526	690
12	**30**	52	438	575
15	**23**	41	350	460

NOTE: Current MEDEVAC Oxygen Cylinder is "D" type.

To estimate duration of use for Oxygen Cylinders:

- Duration of Flow = Contents of cylinder / Flow rate.

Cylinder Factors for Calculation of Duration of Oxygen Flow:

- **Cylinder Size** D E G H and K
  Factor 0.16 0.28 2.41 3.14

Once you have the cylinder factor and the amount of pressure remaining in the cylinder, the duration of flow can be calculated with the following equation.

Duration of flow (min) = Pressure (psig) x Cylinder Factor/Flow (L/min)

Lund-Browder Burn Estimate Chart – Adult

Total Area front/back (circumferential)		one side--anterior	one side--posterior	Do not include in total TBSA

Physician Signature:

JTS BURN RESUSCITATION WORKSHEET

United States Army Institute of Surgical Research Phone Numbers
Comm: (210) 916-2876 (BURN)
DSN: 312-429-2876

Initiate AFTER *completion of trauma assessment and interventions*
Adults only: *Refer to Burn CPG for pediatric specific recommendations*

1. Contact USAISR Burn Center (DSN 312-429-2876) or email: burntrauma.consult.army@mail.mil

Date/Time contact: _____POC:_____ by:_____

2. Estimated Pre-burn Weight (wt): _____kg (Average Service Members are 82 ± 15 kg)

3. Estimate Total Burn Surface Area (TBSA) using Rule of Nines (refine with Lund-Browder after wounds are cleansed)

Partial thickness (2nd)_____% + Full thickness (3rd)_____% = **TBSA**_____%

IF TBSA >40%: intubate (use ETT ≥ 7.5 fr to facilitate bronchoscopy)

IF TBSA <15%: formal resuscitation may not be required, provide maintenance and/or oral fluids

4. Standard Burn Resuscitation Fluid: Lactated Ringers (LR) or Plasmalyte

5. Calculate INITIAL Fluid Rate using Rule of 10 (adults):

- IF wt < 40kg: 2ml x %TBSA_____ x wt(kg)_____ ÷ 16 = _____ml/hr
- IF wt ≥ 40kg: %TBSA_____ x 10 = _____ml/hr
  - IF wt > 80kg: add 100ml/hr to initial rate for every 10 kg>80: adjusted initial fluid rate = _____ml/hr
  - (Example: 100kg patient with 50% TBSA burn = 50% x 10 = 500 ml + 200 ml = 700 ml for first hour)

6. If Inhalation Injury Present: administer aerosolized heparin in albuterol (5,000 units Q4 hours)

7. Titrate Resuscitation Fluid: maintain target **UOP 30-50ml/hr** (Q 1 hour)

- If rhabdomyolysis present: use target UOP 75-100 ml/hr (Contact USAISR Burn Center DSN 312-429-2876)
- Goals: UOP >30 but <50ml/hr; adequate tissue perfusion (normalized lactate/base deficit), MAP >55 mmHg
- Minimum fluid rate 125mL/hr LR
- * Avoid fluid boluses
- ** Too much fluid as dangerous as too little

High risk for over resuscitation/abdominal compartment syndrome:

- If hourly rate >1500mL/hr x 2 hrs OR
- If total 24 hr volume exceeds: wt(kg) x 250ml= _____ml (includes all infused fluids)
  - Contact USAISR Burn Center (DSN 312-429-2876)
  - Consider adjuncts (below)
  - Check bladder pressures Q4hrs (>20 mmHg notify physician)
  - Avoid surgical decompression (significant mortality risk in burns)

Adjuncts:

1. Colloids: 5% albumin/FFP (Hextend only if others unavailable)
   - * Colloids not preferred until hour 8-12; can consider earlier in difficult resuscitation
   - Infuse at ml/hr according to chart below based on adult patient weight and burn size
2. Vasopressors: Contact USAISR Burn Center (DSN 312-429-2876)

5% Albumin Infusion (ml/hr)	30-49%TBSA	50-69% TBSA	70-100% TBSA
<70 kg	30	70	110
70-90 kg	40	80	140
>90 kg	50	90	160

Ensure adequate volume (CVP trend 6-8 cm H_2O); **maintain MAP > 55 mmHg**

JTS BURN RESUSCITATION WORKSHEET

- Maintain ionized Ca >1.1 mmol/L
- Start with vasopressin 0.04mg/min. **DO NOT TITRATE**
- Second line pressor: norepinepherine 2-20mcg/min
- Refractory shock: consider epinephrine or phenylephrine infusion
- Refractory shock: consider adrenal insufficiency, give hydrocortisone 100mg IV Q8 hrs
- Manage acidemia (pH<7.2): use ventilator interventions first, then bicarbonate or THAM infusion
- Renal replacement therapy if available (Contact USAISR Burn Center DSN 312-429-2876)

Assessment/Interventions:

- Complete full secondary trauma exam
- Ensure thermoregulation; administer warmed fluids; cover with space blanket; elevate burned extremities
- Superficial burn (1st degree): Sunburn, no blister, blanch readily; NOT included in TBSA
- Partial thickness (2nd degree): Blanch, moist, blisters, sensate
- Full thickness (3rd degree): Leathery, white, non-blanching, dry, insensate, thrombosed vessels
- Protect eyes with moisture shields if corneas exposed or blink reflex slow; apply ophthalmic erythromycin ointment at least Q2hrs.
- **Prompt intubation for facial burns, suspected inhalation injury, TBSA >40%**
    - Anticipate induction-associated hypotension
    - Secure ETT with cloth tie, not adhesive tape
    - Reassess ETT position at teeth Q1 hr as edema develops and resolves
    - Intubated patients require oro/naso-gastric tube for decompression
    - Administer IV proton-pump inhibitor
- Monitor bladder pressure at least Q4hrs for large burns or high volume resuscitations
    - Abdominal compartment syndrome: decreased UOP, increased pulmonary pressures, difficulty ventilating, bladder pressure remains > 20 mmHg
    - Avoid decompressive laparotomy; consider percutaneous peritoneal drainage
    - Reduce crystalloid volume using colloid or vasopressors
- Monitor pulses hourly: palmar arch, dorsalis pedis, posterior tibial with Doppler
    - Consider escharotomy if signal diminished; refer to Burn CPG for technique (Call USAISR Burn Center DSN 312-429-2876)
- Monitor extremity compartment pressures as clinically indicated
    - Elevate burned extremities at all times
    - Extremity compartment syndrome: pain, paresthesia, pallor, paralysis, pulselessness (late sign)
    - Fasciotomy may be required
- Wound care
    - Thoroughly cleanse burn wounds, preferably in Operating Room
    - Select topical antimicrobial in consultation with Burn Surgeon (Call USAISR Burn Center DSN 312-429-2876) based on product availability, expected transport time, etc
    - Acceptable to cover burns with dry sheets or clean dressings for first 48 hours
- All definitive burn surgery done at USAISR Burn Center for US Service Members (DSN 312-429-2876)

DA Form 4700, Evacuation Patient Care Record (PCR)

1. **BACKGROUND and PURPOSE**
   a. Pre-Hospital, Pre-Medical Treatment Facility (pre-MTF), or inter-MTF evacuation documentation of medical interventions by ground vehicle and rotary-wing based medical personnel (CASEVAC/MEDEVAC) is critical to ensuring continuity of care and providing meaningful analyses of medical interventions, techniques, tactics, and procedures rendered during transport.
   b. As medical providers, it is critically important to document patient care for follow on providers in order to achieve the best patient outcomes. Additionally, well documented care can improve not only individual care, but as part of a Process Improvement system, good documentation can identify places where casualty care can be improved on a system-wide level.
   c. Use of the DA Form 4700, Evacuation Patient Care Record (PCR) will allow for individual care improvement as well as a method to enable appropriate patient care documentation. This will enable process improvement and quality assurance for medical providers rendering care during patient evacuations. It is designed specifically for documentation of care for all patients transported via ground or rotary-wing platforms in order to document all evaluation and care provided for casualties.

2. **POLICY**
   a. Commanders will ensure that all providers evacuating patients (to include both deployed and garrison operations, regardless of AOR) use the PCR to document enroute care. Such care relates to both battle and non-battle injuries.
   b. Once completed, the PCR will be entered into the patient's medical record and the Department of Defense Trauma Registry (DoDTR). Evacuation unit commanders must establish a clear process to ensure transmission of the medical information recorded to the Joint Trauma System for data capture and entry into both the patients' medical record and the DoDTR.
   c. Medical personnel providing care during evacuation will complete all entries as fully as possible.
   d. All abbreviations authorized for use in DoD health records or DoD trauma registries may also be used on the PCR.
   e. This PCR can be completed manually or electronically after care is provided and is designed to work equally well for either. Manual entries may be made using a non-smearing pen or marker.
   f. Free-text may be entered in any block despite appearance of drop-down menus.
   g. Blocks where information is not applicable should be left blank or can be marked "N/A"
   h. In an effort to accurately capture all patient care delivered, providers can document treatments relevant to their transport performed by personnel prior to their assumption of patient care. This care should be documented in the appropriate locations on the form with the time marked as "PTA" (Prior to arrival). (Ex: Ground medic places TQ on RUE prior to MEDEVAC arrival. TQ location, type, etc. should be annotated with time as "PTA").
   i. This form should be completed within 72 hours upon completion of evacuation mission and submitted to JTS ASAP following Medical Director review. Forms can be submitted via NIPR e-mail to: DHA.JBSA.j-3.List.JTS-Prehospital@mail.mil

   j. Additionaly JTS has the Military Enroute Care Registry (MERCuRY) (army.mil). Performance Improvement Events Data worksheet. See instructions on worksheet. Complete the MERCuRY worksheet in conjunction with the DA 4700 before submitting to the Joint Trauma System. (https://jts.amedd.army.mil/assets/docs/forms/MERCuRY_PI_28_Oct_2021.pd)

3. The most current version of the form, along with instructions for use can be found on the JTS site under the documents tab, or at the following address:
   https://jts.amedd.army.mil/index.cfm/documents/forms_after_action

MEDICAL RECORD-SUPPLEMENTAL MEDICAL DATA

  - ☐ Drop off time not recorded
  - ☐ Both times not recorded
- ☐ Role of care not documented
  - ☐ Pick up not recorded
  - ☐ Drop off not recorded
  - ☐ Both not recorded
  - ☐ POI mission
  - ☐ Transfer mission

Circulation /Hemorrhage Control

- ☐ Tourniquet not placed when indicated
- ☐ Tourniquet not reassessed
- ☐ Tourniquet conversion not attempted when indicated
- ☐ Tourniquet time not recorded
- ☐ Tourniquet indicated and successfully performed
- ☐ Type of tourniquet
  - ☐ Limb
  - ☐ Junctional

Airway

- ☐ Deviation from airway management protocol
- ☐ Advanced non-surgical airway placement
  - ☐ Indicated and successfully performed
  - ☐ Performed when not indicated
  - ☐ Not performed when not indicated
  - ☐ Attempted unsuccessfully
- ☐ Cricothyroidotomy
  - ☐ Indicated and successfully performed
  - ☐ Performed when not indicated
  - ☐ Not performed when indicated
  - ☐ Attempted unsuccessfully

Breathing

- ☐ Needle decompression
  - ☐ Indicated and successfully performed
  - ☐ Performed but respiratory distress not resolved
  - ☐ Performed when not indicated
  - ☐ Two or more on the same side
  - ☐ Site not recorded
- ☐ Thoracostomy - finger or tube
  - ☐ Indicated and successfully performed
  - ☐ Performed when not indicated
  - ☐ Not performed when indicated
  - ☐ Attempted unsuccessfully
  - ☐ Two or more on the same side
- ☐ Ventilator management, no ETCO2 recorded
- ☐ Deviation from ventilator management protocol
- ☐ Vent setting changed but no outcome recorded
- ☐ Unplanned extubation enroute

Circulation

- ☐ Rhythm not recorded
- ☐ Blood product transfusion protocol
  - ☐ Indicated and successfully performed
  - ☐ Performed when not indicated
  - ☐ Not performed when indicated
  - ☐ Capability not available
- ☐ IV/IO not inserted enroute when indicated
- ☐ IV/IO insertion unsuccessful
- ☐ Tube or line dislodged enroute

Vitals

- ☐ Appropriate level of monitoring not utilized
- ☐ Vital signs not documented
  - ☐ Blood pressure
  - ☐ Heart rate
  - ☐ Respiratory rate
  - ☐ Sa02
  - ☐ Temperature
- ☐ Hypoxia (SaO2<88%)
  - ☐ Indicated intervention for hypoxia not performed
- ☐ Hypotension (SBP<90 mmHg)
  - ☐ Indicated intervention for hypotension not performed
- ☐ GCS or AVPU not documented
- ☐ GCS or AVPU changes not documented
- ☐ Pain assessment not completed

Additional Interventions

- ☐ Immobilization not performed when indicated
  - ☐ C-collar
  - ☐ Pelvic binder
  - ☐ Spinal motion restriction
  - ☐ SAM splint for extremity
  - ☐ Rigid eye shield
- ☐ Hypothermia prevention not initiated when indicated

Medications

- ☐ Pain medication not given per protocol
- ☐ Pain medication given, outcome undocumented
- ☐ TXA not given <3 hrs after injury when indicated
- ☐ Antibiotic not given per protocol
- ☐ Other medication delay or complication (please specify)

Notes

Other

- ☐ Documentation from sending provider did not accompany patient (TCCC card or patient chart)
  - ☐ Absent documentation from ground team
- ☐ Diversion of flight or unplanned destination
- ☐ Incomplete hand off from ground team
- ☐ Equipment problem, unable to be resolved enroute
- ☐ Environmental issues affecting patient outcome
- ☐ Death or CPR enroute
- ☐ Missing needed gear or medications
- ☐ Events enroute precluding adequate patient monitoring/assessment/treatment
- ☐ Other (please specify in Notes)

Notes & Comments

Instructions

1. Complete the Mercury in conjunction with the 4700 before submitting to the Joint Trauma System.
2. Enroute care should be assessed for compliance with standard guidelines to include: Tactical Combat Casualty Care guidelines, Standard Medical Operating Guidelines, JTS Intratheater transport clinical practice guide.
3. At least two unique patient identifiers are needed for documenting patient identification.
4. One identifier must be last name, BR#, or SSN. The second identifier can be first name, BR#, SSN, DOB, or unit.
5. Hemorrhage control, Airway, Breathing, Circulation, Vitals, Additional Interventions, Medications: Evaluate enroute interventions only. Do not evaluate interventions performed prior to MEDEVAC.
6. Other-incomplete handoff from ground team: Review narrative for comments relating to incomplete or inadequate handoff.

INSTRUCTIONS: DD Form 1380, Tactical Combat Casualty Care (TCCC) Card
[Formerly: U.S. Field Medical Card]

1. BACKGROUND and PURPOSE

a. Pre-Hospital or Pre-Medical Treatment Facility (pre-MTF) documentation of medical interventions by first responders at the point of injury (POI) is critical to ensuring continuity of care and providing meaningful analyses of medical interventions, techniques, tactics, and procedures rendered at the POI.

b. In a deployed, combat, or training setting, all personnel have the potential to be casualties and all personnel have the potential to be first responders.

c. In accordance with Joint Publication 4-02, Health Service Support, dated 26 July 2012: "First responder care capability is also known as tactical combat casualty care. Tactical combat casualty care [or TCCC] occurs during a combat mission and is the military counterpart to pre-hospital trauma life support. Pre-hospital trauma care in the military is most commonly provided by enlisted personnel and includes self-aid and buddy aid and combat life savers.... Tactical combat casualty care focuses on the most likely threats, injuries, and conditions encountered in combat and on a strictly limited range of interventions directed at the most serious of these threats and conditions...."

d. DD Form 1380 promotes Department of Defense goals of capturing documentation of pre-MTF medical interventions at the POI using a MIST format (Mechanisms of injury; Injuries; Signs & Symptoms; and Treatments). It is designed for use by all first responders, including non-medical personnel.

2. POLICY

a. Commanders will ensure that all first responders carry and use DD Form 1380 to document pre-MTF care at the POI. Such care relates to both battle and non-battle injuries.

b. Once completed, DD Form 1380 must be visibly attached to the patient. Upon arrival at a Role 2 or Role β MTF, DD Form 1380 will be included with the paper medical record, then scanned and entered into both the patient's electronic health record and the trauma system's trauma registry. Role 2 and Role 3 MTF commanders must establish a clear process to ensure entry of the medical information recorded on DD Form 1380 into the both the electronic health record and the trauma registry.

c. DD Form 1380 will be a component of the individual/improved first aid kit (IFAK), joint first aid kit (JFAK), and other first aid kits utilized. Corpsmen, combat medics, and tactical evacuation personnel should carry multiple blank versions of the form.

d. First responders will complete all entries as fully as possible on the DD Form 1380 unless under extreme conditions whereby the casualty and/or provider's safety may be at additional risk.

e. Detailed instructions for preparing DD Form 1380 are provided in Table 1 and Table 2.

f. All abbreviations authorized for use in DoD health records or DoD trauma registries may also be used on DD Form 1380.

g. All entries on the DD Form 1380 will be made using a non-smearing pen or marker.

h. All entries on the DD Form 1380 should be printed clearly, including the first responder's name.

Table 1: Instructions for completing DD Form 1380 (Front of Card)

Item	Instructions
Battle Roster #	Write first letter of casualty's first name, then first letter of casualty's last name, then write the last four numbers of casualty's Social Security number. For example, John Doe 123-12-1234 is Battle Roster # "JD1234".
Evacuation (EVAC)	Mark an "X" on the casualty's evacuation priority/precedence (Urgent; Priority; or Routine).
Name	Write casualty's name (Last, First).
Last 4	Write last four numbers of casualty's Social Security number.
Gender	Mark an "X" on the casualty's gender (Male (M) or Female (F)).
Date	Write date of injury in DD-MMM-YY format. For example, "29-JUN-13".
Time	Write 24 hour time of injury, and indicate whether local (L) or zulu (Z) time. For example, "1300Z".
Service	Write casualty's branch of service (USA, USAF, USCG, USN, USMC). For U.S. civilians, write "US CIV". For non-U.S. personnel, write "NON US or a standard abbreviation for casualty's nationality.
Unit	Write casualty's unit name.
Allergies	Write casualty's known drug allergies. If no drug allergies, write "NKDA" (no known drug allergies).
Mechanism of Injury	Mark an "X" on the mechanism or cause of injury (artillery, blunt, burn, fall, grenade, gunshot wound (GSW), improvised explosive device (IED), landmine,

INSTRUCTIONS: DD Form 1380, Tactical Combat Casualty Care (TCCC) Card
[Formerly: U.S. Field Medical Card]

Item	Instructions
	motor vehicle crash/collision (MVC), rocket-propelled grenade (RPG), other (specify)). Mark all that apply.
Injury	Mark an "X" at the site of the injury(ies) on the body picture. For burn injuries, circle the burn percentage(s) on the figure. If multiple mechanisms of injury and multiple injuries, draw a line between the mechanism of injury and the anatomical site of the injury.
TQ: R Arm (tourniquet, right arm)	If a tourniquet is applied to the right arm, write type of tourniquet used and the time of tourniquet application.
TQ: L Arm (tourniquet, left arm)	If a tourniquet is applied to the left arm, write type of tourniquet used and the time of tourniquet application.
TQ: R Leg (tourniquet, right leg)	If a tourniquet is applied to the right leg, write type of tourniquet used and the time of tourniquet application.
TQ: L Leg (tourniquet, left leg)	If a tourniquet is applied to the left leg, write type of tourniquet used and the time of tourniquet application.
Time, Pulse (rate & location), Blood Pressure, Respiratory Rate, Pulse Ox % O2 Sat, AVPU, Pain Scale (0-10)	Record vital signs (pulse rate and location, blood pressure, respiratory rate, oxygen saturation), level of consciousness (AVPU: Alert, responds to Verbal stimulus, responds to Pain stimulus, Unresponsive), and level of pain (on numeric rating scale of 0 to 10, with 0 being no pain and 10 being the worst pain) with time.

Table 2: Instructions for completing DD Form 1380 (Back of Card)

Item	Instructions
Battle Roster #	Write first letter of casualty's first name, then first letter of casualty's last name, and then write the last four numbers of casualty's Social Security number. For example, John Doe 123-12-1234 is Battle Roster # "JD1234".
Evacuation (EVAC)	Mark an "X" on the casualty's evacuation priority/precedence (Urgent; Priority; or Routine).
C	Mark an "X" for all Circulation hemorrhage control interventions. For tourniquets (TQ), mark category (Extremity, Junctional and/or Truncal) and write name of TQ(s) used. For dressings, mark category (Hemostatic, Pressure, and/or Other) and write type of dressing(s) used.
A	Mark an "X" for all Airway interventions (Intact, NPA (nasopharyngeal airway), CRIC (cricothyroidotomy), ET Tube (endotracheal tube), SGA (supraglottic airway) and write type of device(s) used.
B	Mark an "X" for all Breathing interventions (O2 (oxygen), Needle-D (needle decompression), Chest-Tube, Chest-Seal) and write type of device(s) used.
C: Fluid	Circulation resuscitation interventions. Write name, volume, route, and time of any fluids given.
C: Blood Product	Circulation resuscitation interventions. Write name, volume, route, and time of any blood products given.
Meds: Analgesic	Medications. Write name, dose, route, and time of any analgesics given.
Meds: Antibiotic	Medications. Write name, dose, route, and time of any antibiotics given.
Meds: Other	Medications. Write name, dose, route, and time of any other administered medications.
Other	Mark an "X" for other treatments administered (combat pill pack, eye shield (mark right (R) or left (L)), splint, hypothermia prevention) and type of device(s) used.
Notes	Use this space to record any other pertinent information and/or clarifications.
First Responder Name	Print the first responder's name (Last, First).
First Responder Last 4	Write last four numbers of first responder's Social Security number.

General instruction for Canine Trauma Combat Casualty Care Card

PURPOSE: The Canine Tactical Combat Casualty Care (cTCCC) card is for documenting a trauma or disease non-battle injury (DNBI) at the point of injury anywhere a canine is deployed in support of DoD operations. The cTCCC card will be filled out by the handler or provider who attends to the canine's trauma or DNBI. After medical treatment and resuscitation care is provided, the cTCCC card can be handed off to the nearest veterinary treatment facility or supporting veterinary unit to be scanned, uploaded and emailed to dog.consult@us.af.mil or the unit providing care can email directly. Once the MWD Trauma Registry is online, the first veterinary unit can input the information into the registry and scan the cTCCC card to upload into ROVR. The cTCCC card becomes part of the canine's permanent DoD medical record. For US Special Operations Command (SOCOM) canines, the cTCCC card will be filled out and returned to the handler or operator. The handler or operator will route the card to their respective veterinarian to be inputted into the MWD Trauma Registry and the canine's record.

PAGE 1:

GENERAL INSTRUCTIONS

- To be completed by the handler, human medical provider, veterinary technician or veterinarian fulfilling the role at the point of injury.
- Time Zones: Record all time local 24 hour military format, hh:mm
- A+ (plus sign) means positive test result; a - (minus sign) means negative test result.

EVACUATION CATEGORY (mark as appropriate)

URGENT – Patient who should be evacuated as soon as possible and within **two** hours to save life, limb or eyesight

PRIORITY – Patient who should be moved within **four** hours or their condition will deteriorate to such a degree that will be urgent

ROUTINE – Patient whose condition is not expected to worsen significantly and who will require evacuation in the next **24** hours

EVACUATION MODE & TYPE (mark as appropriate)

PATIENT IDENTIFICATION

UNIT. Record the unit the canine is assigned

ANIMAL NAME. (self-explanatory)

TATTOO. (self-explanatory)

DATE. (DD-MM-YY)

TIME. Record all time local 24 hour military format, hh:mm

GENDER. (mark as appropriate)

MECHANISM OF INJURY (mark as appropriate – use other for DNBI or if unknown – describe)

INJURY (mark the diagram where the trauma/injury or disease is located – if there are more than one injury, identify each with the mechanism of injury)

VITAL SIGNS (input vital signs at least hourly)

Pain Score:

0 – Pain free

1 – Very minor annoyance-occasional minor twinges

2 – Minor annoyance-occasional

3 – Annoying enough to be distracting

4 – Can be ignored if you are really involved in your work, but still distracting,

5 – Can't be ignored for more than 30 minutes.

6 – Can't be ignored for any length of time, but you can still go to work and participate in social activities.

7 – Make it difficult to concentrate, interferes with sleep, you can still function with effort

8 – Physical activity severely limited. You can read and converse with effort. Nausea and dizziness may occur.

9 – Unable to speak, crying out or moaning uncontrollable- pain makes you pass out

10 – Unconscious. Pain makes you pass out.

FIRST RESPONDERS (self-explanatory)

PAGE 2:

TREATMENTS (mark as appropriate) and annotate location where appropriate

M (Massive Hemorrhage): (mark as appropriate)

A (Airway Control): self-explanatory

R (Respiratory Support): self-explanatory

C (Circulation): FLUIDS (fill out as appropriate and complete as possible)

C (Fracture): self-explanatory

H (Hypo/hyperthermia): self-explanatory

H (Head Injury): self-explanatory

MEDICATIONS (MEDS) (Circle the medication given and write the time given in the notes)

NOTES (Include any additional information (location/country, euthanized/KIA, treatment regiments that were used to the treat the patient etc.)

DISPOSITION OF THE FORM – (The form is to be kept with the patient until it can be put into the patient's record.) Pass the card to the next treatment facility. 1) Scan and email the card to dog.consult@us.af.mil . 2) Put the card into the patient's hard copy record. CAVEAT: For US Special Operations Command (SOCOM) canines, the cTCCC card will be filled out and returned to the handler or operator. The handler or operator will route the card to their respective veterinarian to be inputted into the MWD Trauma Registry and the canine's record.

DEFINITIONS

IED – Improvised explosive device
GSW – Gunshot wound
TQ – Tourniquet
ET – Endotracheal tube
TXA – Tranexamic acid

DISTRIBUTION: US ARMY TRAINING SUPPORT CENTERS (TSCs)
HEADQUARTERS, DEPARTMENT OF THE ARMY,
ATTN: ATIC-SAA, GTA Program, Fort Eustis, VA 23604-5166

LINE ITEM	EXPLANATION
1. Location of Pickup Site.	Encrypt grid coordinates. When using *DRYAD Numeral Cipher, the same SET line* will be used to encrypt grid zone letters and coordinates. To preclude misunderstanding, a statement is made that grid zone letters are included in the message (unless unit SOP specifies its use at all times).
2. Radio Frequency, Call Sign, Suffix.	Encrypt the frequency of the radio at the pickup site, *not* a relay frequency. The call sign (and suffix if used) of person to be contacted at the pickup site may be transmitted in the clear.
3. No. of Patients by Precedence.	Report only applicable info & encrypt brevity codes. A = Urgent, B = Urgent-Surg, C = Priority, D = Routine, E = Convenience. (If 2 or more categories reported in same request, insert the word "break" btwn. each category.)
4. Spec Equipment.	Encrypt applicable brevity codes. A = None, B = Hoist, C = Extraction equipment, D = Ventilator.
5. No. of Patients by Type.	Report only applicable information and encrypt brevity code. If requesting MEDEVAC for both types, insert the word *"break"* between the litter entry and ambulatory entry: L + # of Pnt -Litter; A + # of Pnt - Ambul (sitting).
6. Security Pickup Site (Wartime).	N = No enemy troops in area, P = Possibly enemy troops in area (approach with caution), E = Enemy troops in area (approach with caution), X = Enemy troops in area (armed escort required).
6. Number and type of Wound, Injury, Illness (Peacetime).	Specific information regarding patient wounds by type (gunshot or shrapnel). Report serious bleeding, along with patient blood type, if known.
7. Method of Marking Pickup Site.	Encrypt the brevity codes. *A* = Panels, *B* = Pyrotechnic signal, *C* = Smoke Signal, *D* = None, *E* = Other.
8. Patient Nationality and Status.	Number of patients in each category need not be transmitted. Encrypt only applicable brevity codes. A = US military, B = US civilian, C = Non-US mil, D = Non-US civilian, E = EPW.
9. NBC Contamination, (Wartime).	Include this line only when applicable. Encrypt the applicable brevity codes. N = nuclear, B = biological, C = chemical.
9. Terrain Description (Peacetime).	Include details of terrain features in and around proposed landing site. If possible, describe the relationship of site to a prominent terrain feature (lake, mountain, tower).

Value equals amount of fluid in each ml of dilution

Each ml of medication diluted into your chosen fluid still counts towards total solution volume (i.e. 1ml of drug + 4ml fluid = 5ml solution; 1ml drug + 9ml fluid = 10ml solution). Small volume medications (1-2ml) are inconsequential above dilutions >50ml

1mg=1000mcg | 0.1mg=100mcg | 0.01mg=10mcg

STANDING ORDERS - Air Ambulance, Emergency Medicine Tasks

PURPOSE

The intended purpose of these guidelines is to serve as a baseline for the Aviation Medical Company's Aviation Medicine SOP (Standing Orders and Aeromedical Treatment Guidelines). Practices in Aviation Medicine undergo constant scrutiny and change. As such, this guide should not be considered an all-inclusive and always up-to-date source of the newest and most relevant policies, procedures, and practices in Aviation Medicine. It will require continued monitoring for relevant clinical and operational updates needed to reflect current aviation and clinical practice standards.

Primarily, this guide should serve as a resource for tactical and non-tactical prehospital, interfacility and post-surgical enroute medical care on an Army aeromedical platform. Initial patient evacuation and prehospital trauma guidelines are written in a manner to support the principles of Tactical Combat Casualty Care (TCCC). This assumes that a combat trauma patient will respond to care most effectively when the order of care addresses circulation (stopping and preventing hemorrhage) prior to addressing the patient's airway and breathing. When these guidelines are adapted for use within US Army civilian missions (noncombat), unit medical directors should consider the necessity of writing and appending these guidelines, order of care, and standard operating procedures to address the differences in initial interventions of the civilian trauma patient verses the combat trauma patient.

SCOPE OF PRACTICE

This guide is intended for use by Aviation Medical Personnel to include: Critical Care Flight Paramedics, Flight Surgeons, Aeromedical Physician Assistants (APAs), Aeromedical Nurse Practitioners (ANPs), and En Route Critical Care Nurses performing MEDEVAC on an Army Aviation platform. Preferably, only medical personnel trained in and holding certifications in the National Registry of Paramedics (NRP), Emergency Medicine, or Critical Care should be eligible to use all treatment guidelines within this book. However, local training programs may be adopted that may enable individually trained physicians, Physician Assistants, and Non-NRP Flight Medics a knowledge base sufficient to satisfy use of these treatment guidelines in an austere/combat environment. Specific certifications of importance might include: TCMC, ATLS®, ACLS/ALS, PALS, PHTLS, ITLS, and PEPP, among others. Any individual who is not fully trained, has not demonstrated competency in each of these guidelines, or has not been approved (credentialed) to use these guidelines by the local Aviation Medicine Medical Director should not be authorized to perform the respective guideline(s) without direct (on-hand) oversight. All personnel using these guidelines should adhere to the steps and standards as outlined in each of the standard medical operating guidelines (SMOG) and procedures. Moreover, all unit medical personnel providing care aboard US Army Air Ambulances (including Unit Flight Surgeons and APAs) will, at a minimum, adhere to this standard of care unless superseded by theater and/or regional clinical practice guidelines under the authorization of an appropriate local command medical officer/surgeon.

Following the concept set forth in the National Emergency Medical Services (EMS) Scope of Practice Model, an individual may only perform a skill or role for which that person is:

• educated (has been trained to do the skill or role), AND
• certified (has demonstrated competence in the skill or role), AND
• licensed [has legal authority issued by the State (Army EMS is the 51st State) to perform the skill or role], AND
• credentialed (has been authorized by medical director to perform the skill or role).

Depending on the military environment (deployed or austere location), licensing and credentialing may be satisfied through a local training and standardization policy that demonstrates an individual medical provider's capabilities and knowledge of the treatment guidelines within this handbook. Approval of each individual provider's usage of these treatment guidelines must be provided by the unit medical director. This approval should be documented and maintained in the Soldiers training record.

It must be remembered that any use of these guidelines is prohibited outside of the individual's military employment. Furthermore, any civilian based medical care provided by aviation medicine personnel must satisfy the National EMS Scope of Practice Model noted previously. It must also be realized that any usage of these guidelines within the civilian environment may be limited to support through a legitimate local EMS credentialing provider. This would normally be the local Medical Treatment Facility Emergency Medical Systems credentialing authority. The unit medical director may or may not satisfy this requirement in civilian medicine due to state laws, policies, or standards.

USAGE INTENT

This guide contains the specific Treatment Guidelines, Procedures, and Medications that will be used within Army Aeromedical Evacuation.

The Critical Care Flight Paramedic Standard Medical Operating Guideline will be reviewed at a minimum semi-annually or upon change of command or medical director. A single copy of the Review and Approval Page or a substitute document will be distributed to aforementioned individuals for review and approval signatures.

It is the responsibility of the Unit Commander, the Medical Director, the Training NCO, and the Standards NCO to ensure that all Flight Paramedics remain current in all required certifications needed to perform their duties as Flight Paramedics and/or those needed to perform the skills of a Nationally Registered Paramedic. This should include, at a minimum, certifications in NRP, ALS/ACLS, and BLS. However, it is highly recommended that paramedics maintain certifications in PALS/PEPP and PHTLS/ITLS. Copies or originals of all current certifications or a memo of training status/credentials will be maintained in the individual Soldier's training record.
A medical practitioner's clinical competence is at least equal in importance to the maintenance of formal certifications. Competence is the ability to actually perform required interventions and administer appropriate therapies. A competent practitioner has the knowledge base and critical-thinking skill required to determine when to perform an intervention and when it is best NOT to do so. Commanders and Unit Medical Directors/ Flight Surgeons should ensure that clinical skill competency is maintained, demonstrated, and remediated (when required) to ensure the maintenance of skills and mandated certifications of medical aircrew members under their direction. It is recommended that all medical personnel conducting aeromedical evacuation

perform simulated critical care and POI training cases on a monthly basis in order to develop competency and retain critical care medical proficiency.

The Flight Paramedic Standard Medical Operating Guideline is not intended to be a comprehensive patient care manual. Rather, it specifies standard clinical treatment guidelines for discrete emergency conditions which should be used as a baseline practice standard for Flight Paramedics and other attached medical aircrew members providing enroute emergency care on a rotary wing platform in the prehospital environment while conducting intratheater, CONUS, or other tactical/operational contingency missions.

QUALITY MANAGEMENT PROGRAM Procedures

Physician Medical Direction

Prehospital emergency care constitutes the practice of medicine, either directly by a qualified physician or indirectly through delegation-of-authority under the physician's medical direction. This practice is distinctly different from hospital-based medical, nursing, and paramedical practice in which practitioners conduct full-spectrum care within their respective scope-of practice, executing physician's orders, or through autonomous practice in the case of Physician Assistants (PA), Nurse Practitioners (NP), and Clinical Nurse Specialists (CNS).

Medical direction of Flight Paramedics and other medical aircrew with regard to procedures, guidelines, medications, documentation (Patient Care Reports), testing, credentials, etc., is the primary responsibility of the qualified (as defined by AR 40-3) assigned Flight Surgeon (FS) (normally a Battalion Surgeon), with the assistance of the Aeromedical Physician Assistant (APA) and designated company Medical Training NCO. The Brigade Surgeon has responsibility for overall medical oversight. All medical aircrew should maintain currency on recent literature and equipment pertaining to pre-hospital aeromedical evacuation and enroute care.

Advanced-Care Provider Clinical Oversight

Although they cannot act as a medical director, the role of PAs, NPs and CNSs in the practice of prehospital emergency care is emerging and holds great promise as a means of extending the medical director's capacity to ensure the best quality of care for patients or casualties. While Federal Regulations and most State Laws pertaining to EMS require physician medical direction for the prehospital conduct of advanced life support (ALS) scope-of-practice skills, many high performance domestic EMS systems have implemented mid-level "clinical director" programs, employing PAs and advanced practice nurses with emergency or critical care expertise, to provide initial quality management program (QMP) review, assist with on-line decision support for pre-hospital practitioners, oversee readiness training and continuing education, and to augment the medical aircrew when needed on ground and air critical care transport platforms. PAs, with the approval of the Brigade Surgeon, can provide the necessary clinical oversight in the absence of a unit level Flight Surgeon in order to ensure the CCFPs are trained and proficient for their deployed mission.

Quality Assurance

Published Standard Medical Operating Guidelines (SMOG) are written patient care guidance in algorithm format with discrete basic life support (BLS) and advanced life support (ALS) scopes of practice, respectively, based on each patient / casualty's specific medical condition. Once endorsed by local commanders and unit medical directors, all medical aircrew are expected to use these guidelines in the care of patients they transport to the next higher level of care. Periodically, medical aircrew should undergo testing on information and procedures contained within these guidelines. After each patient that has been aero-medically evacuated to a Role 2 or Role 3 medical treatment facility, each medical aircrew member is responsible for documenting the care rendered during transport via the appropriate unit, theater, or DA / DD approved / mandated electronic or written patient care documentation form

Direct Supervision

In addition to the written guidelines, designated unit medical directors are responsible for the direct supervision of medical aircrew members participating in en route care within the unit, his/her performance in situations in which the patient's medical condition(s) does not meet standard-of-care as defined by these guidelines, or who experience adverse events en route, merit retrospective review and determination of root cause and corrective action, or endorsement of their decision, as appropriate.

Quality Management/Process Improvement

After each Aeromedical Evacuation mission, for each patient receiving enroute care, the medical aircrew team conducts an informal After Action Review (AAR). The initial formal control measure is the requirement for the FS or APA to review and co-sign each patient care report (PCR) (e.g., DD 1380, run sheet, Enroute Critical Care Transfer document, DD4700) before it is submitted as a part of the patient record. After both the lead medical aircrew member and unit medical director have signed the PCR, a copy will be kept and others will be distributed in accordance with current Army policy guidelines, local unit policy, and by the medical training NCO and/or medical director.

Additional quality control measures are encouraged and can foster a rich and open learning environment between local emergency medicine/trauma facilities and members of the air ambulance company. One such option might include a monthly aeromedical evacuation conference chaired by the local MTF Trauma Surgeon in which medical aircrew member's present cases to a forum of providers and other medics with emphasis on best practices and lessons learned.

UPDATE and APPROVAL PROCESS

1. The Critical Care Flight Paramedic Standard Medical Operating Guidelines will be updated generally on an annual basis, or sooner in response to clinical or operational needs.

2. Based upon the above timeframes, the Director, Department of Aviation Medicine (DAM) should initiate an update by sending the SMOG for inputs from senior aeromedical clinicians (flight surgeons, aeromedical physician assistants, and aeromedical nurse practitioners), emergency medicine physicians, EMS trained physicians, and critical care flight paramedic end-users.

3. Suspense for submitting updates back to an identified editor will be a minimum of 30 calendar days. Extensions may be granted on a case by case basis.

4. The editor will consolidate all inputs and discuss with a designated physician (as identified by the Director, DAM).

5. After all accepted/applicable inputs have been updated; the SMOG will receive final approval from Director, DAM.

6. Once final approval is given, the SMOG will undergo OPSEC/PAO review prior to posting.

POINT OF INJURY CARE, TCCC Evacuation Phase Guideline

INDICATIONS: In combat, the period of care provided at the Point of Injury (POI) is the most critical period throughout a casualty's movement across the medical system. Timely, appropriate, and effective care at the POI will afford a casualty the greatest chance of surviving preventable causes of death regardless of necessary follow-on surgical interventions and specialty medical treatment.

GUIDELINE (see TACTICAL EVACUATION Guideline). This guideline serves as the starting point for initiation of care for all patients evacuated from the POI pick-up sight. All subsequent procedural steps of care will be determined by navigation through continued guideline flow charts. All care will be provided in accordance with these flow charts.

POLICY NOTE: In the event these guidelines are adapted for use within US Army civilian missions (non-combat), it is recommended that unit medical directors consider the necessity of writing and appending these guidelines, order of care, and standard operating procedures to address the differences in initial interventions of the civilian trauma patient verses the combat trauma patient.

MEDICAL DIRECTOR / UNIT COMMANDER

REVIEW AND APPROVAL PAGE

It is the responsibility of the Unit Commander, the Medical Director, the Training NCO, and the Standards NCO to ensure that all Flight Paramedics remain current in all required certifications needed to perform their duties as Flight Paramedics and/or those needed to perform the skills of a Nationally Registered Paramedic. This includes, at a minimum, certifications in NRP, ACLS/ALS, and BLS. Copies or originals of all current certifications will be placed maintained in the individual Soldiers training record. It is recommended that all CCFP level providers maintain PALS certifications and Flight Paramedic- Certified (FP-C) certifications.

The Standard Medical Operating Guideline is not intended to be a comprehensive patient care manual. Rather, it specifies standard medical treatment guidelines to be used by all Flight Paramedics and Medical Providers performing medical care while serving in this unit in an austere, deployed, or garrison environment.

This document has been reviewed by the below noted individuals for correctness, and mission applicability.

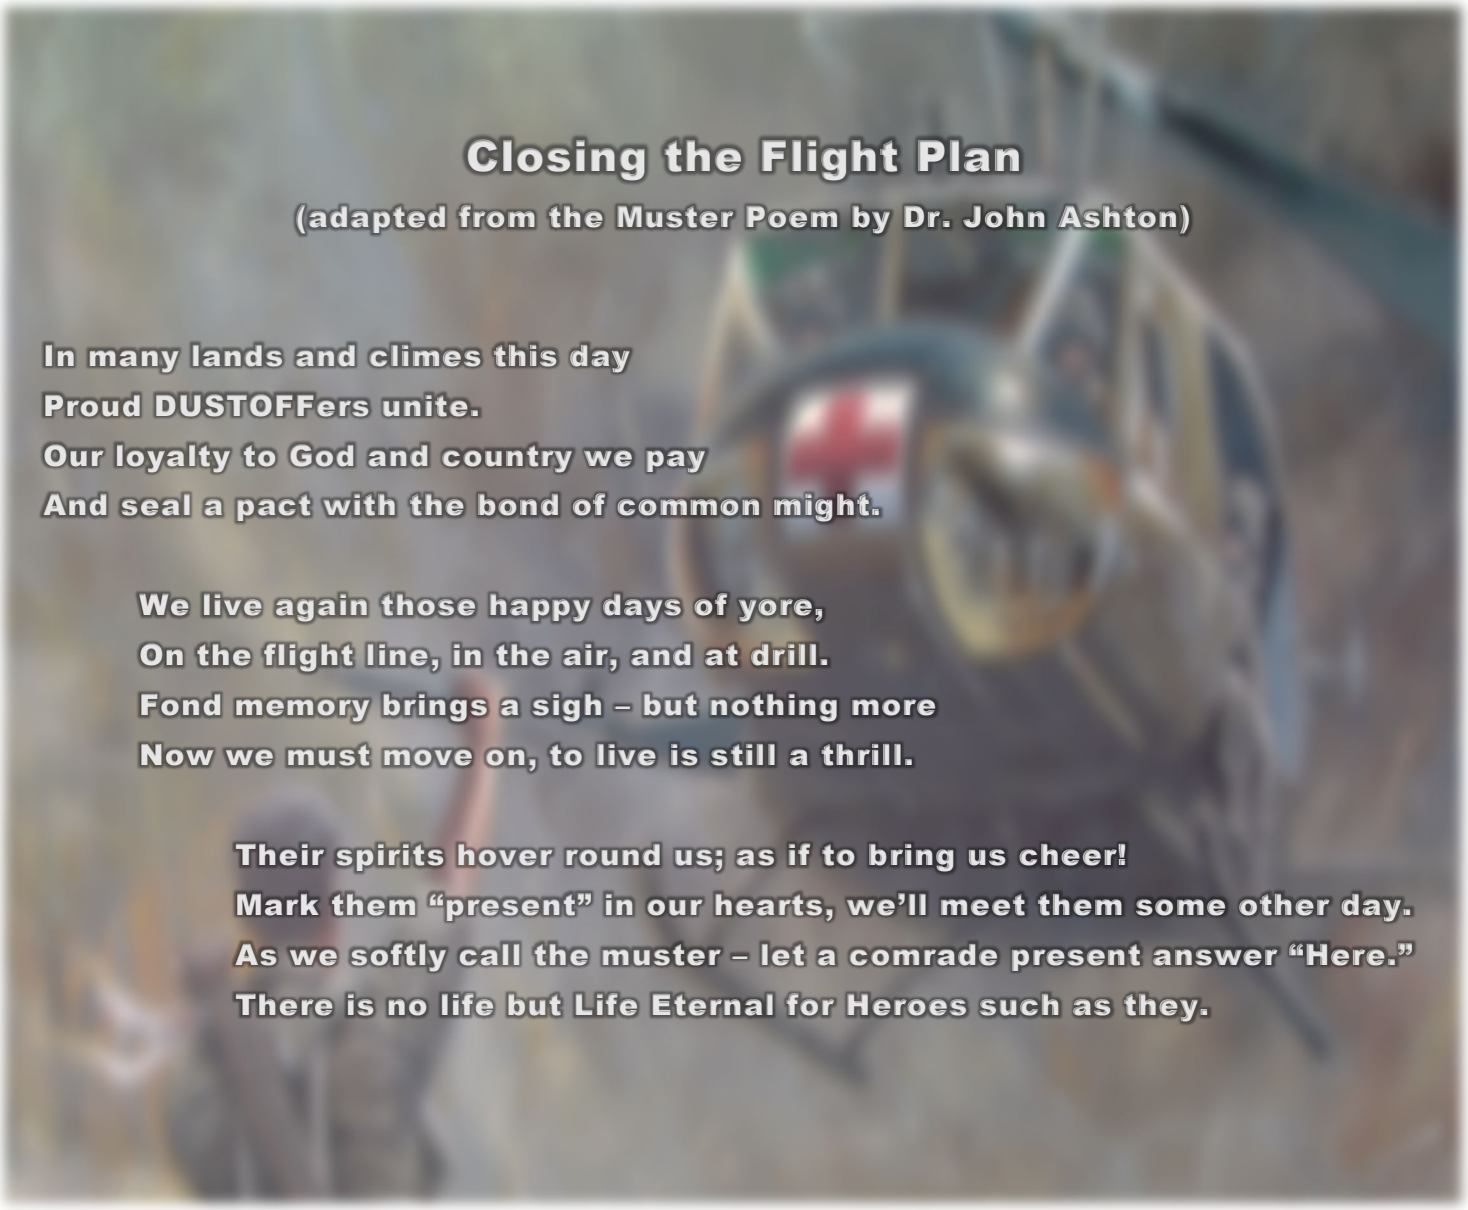
Additional Medical Director comments and addendums can be attached and should contain counter signature of unit commander for validity.

The Critical Care Flight Paramedic Standard Operating Guidelines are dedicated to our past, present and future DUSTOFF aircrews who un-hesitantly go into harm's way so that other may live. May you forever be protected by angel's wings within the heaven's on which men fly.



Closing the Flight Plan
(adapted from the Muster Poem by Dr. John Ashton)
In many lands and climes this day
Proud DUSTOFFers unite.
Our loyalty to God and country we pay
And seal a pact with the bond of common might.
We live again those happy days of yore,
On the flight line, in the air, and at drill.
Fond memory brings a sigh – but nothing more
Now we must move on, to live is still a thrill.
Their spirits hover round us; as if to bring us cheer!
Mark them "present" in our hearts, we'll meet them some other day.
As we softly call the muster – let a comrade present answer "Here."
There is no life but Life Eternal for Heroes such as they.

Summary of Changes

Page numbers added to all pages. ***NOTE***: Clicking on page numbers sends the reader to the Table of Contents. Items listed on the Table of Contents link directly to the page described. All other previous hyperlinks are disabled.

Protocols Updated

- *Introduction and Table of contents*
- Head Injury/TBI
- Sepsis
- Stroke
- All Cardiac (adult and Ped) Protocols. Now reflect American Red Cross standards
- All Pediatric Protocols. Now reflect American Red Cross PALS standards
- Hypertension
- All MWD Protocols.
- Airway Pearls
- Rapid Sequence Intubation
- Ventilator Management
- Enroute Damage Control Resuscitation
- Pain Management
- Standing Orders
- CDR/Medical Director Approval

Drug Cards Updated

- SMOG Drug Card/Chart
- Atropine
- Calcium Chloride
- Epi 1:10,000 Drip Chart
- Ketamine
- Labetalol
- Midazolam
- Propofol
- Rocuronium
- Tranexamic Acid (TXA)
- Vecuronium

NOTE:

There are many changes throughout the SMOG. Individuals should not just rely on the summary of changes page alone to be up to date on all contents within the SMOG. It is strongly encouraged that individuals go through all the SMOG in its entirety.

Tactical Combat Casualty Care (TCCC) Guidelines for Medical Personnel

15 December 2021

RED text indicates new text in this year's update to the TCCC Guidelines; **BLUE text** indicates text that did not change but was relocated within the guidelines. Recent changes include junctional and airway device recommendations, analgesia, and abdominal evisceration guidelines.

Basic Management Plan for Care Under Fire/Threat

1. Return fire and take cover.

2. Direct or expect casualty to remain engaged as a combatant if appropriate.

3. Direct casualty to move to cover and apply self-aid if able or when tactically feasible, move or drag casualty to cover.

4. Try to keep the casualty from sustaining additional wounds.

5. Casualties should be extracted from burning vehicles or buildings and moved to places of relative safety. Do what is necessary to stop the burning process.

6. Stop life-threatening external hemorrhage if tactically feasible:
    a. Direct casualty to control hemorrhage by self-aid if able.
    b. Use a CoTCCC-recommended limb tourniquet for hemorrhage that is anatomically amenable to tourniquet use.
    c. Apply the limb tourniquet over the uniform clearly proximal to the bleeding site(s). If the site of the life-threatening bleeding is not readily apparent, place the tourniquet "high and tight" (as proximal as possible) on the injured limb and move the casualty to cover.

7. Airway management is generally best deferred until the Tactical Field Care phase.

Basic Management Plan for Tactical Field Care

1. **Establish a security perimeter in accordance with unit tactical standard operating procedures and/or battle drills. Maintain tactical situational awareness.**

2. **Triage casualties as required. Casualties with an altered mental status should have weapons and communications equipment taken away immediately.**

3. **Massive Hemorrhage**

    a. Assess for unrecognized hemorrhage and control all sources of bleeding. If not already done, use a CoTCCC-recommended limb tourniquet to control life-threatening external hemorrhage that is anatomically amenable to tourniquet use or for any traumatic amputation. Apply directly to the skin 2-3 inches above the bleeding site. If bleeding is not controlled with the first tourniquet, apply a second tourniquet side-by-side with the first.
    b. For compressible (external) hemorrhage not amenable to limb tourniquet use or as an adjunct to tourniquet removal, use Combat Gauze as the CoTCCC hemostatic dressing of choice.
        - Alternative hemostatic adjuncts:
            - Celox Gauze or
            - ChitoGauze or
            - XStat (best for deep, narrow-tract junctional wounds)
            - iTClamp (may be used alone or in conjunction with hemostatic dressing or XStat)
        - Hemostatic dressings should be applied with at least 3 minutes of direct pressure (optional for XStat). Each dressing works differently, so if one fails to control bleeding, it may be removed and a fresh dressing of the same type or a different type applied. (Note: XStat is not to be removed in the field, but additional XStat, other hemostatic adjuncts, or trauma dressings may be applied over it.)
        - If the bleeding site is amenable to use of a junctional tourniquet, immediately apply a junctional tourniquet. Do not delay in the application of the junctional tourniquet once it is ready for use. Apply hemostatic dressings with direct pressure if a junctional tourniquet is not available or while the junctional tourniquet is being readied for use.
    c. For external hemorrhage of the head and neck where the wound edges can be easily re-approximated, the iTClamp may be used as a primary option for hemorrhage control. Wounds should be packed with a hemostatic dressing or XStat, if appropriate, prior to iTClamp application.
        - The iTClamp does not require additional direct pressure, either when used alone or in combination with other hemostatic adjuncts.
        - If the iTClamp is applied to the neck, perform frequent airway monitoring and evaluate for an expanding hematoma that may compromise the airway.

Consider placing a definitive airway if there is evidence of an expanding hematoma
- DO NOT APPLY on or near the eye or eyelid (within 1cm of the orbit).

d. Perform initial assessment for hemorrhagic shock (altered mental status in the absence of brain injury and/or weak or absent radial pulse) and consider immediate initiation of shock resuscitation efforts.

4. Airway Management

a. Conscious casualty with no airway problem identified:
   - No airway intervention required
b. Unconscious casualty without airway obstruction:
   - Place casualty in the recovery position
   - Chin lift or jaw thrust maneuver or
   - Nasopharyngeal airway or
   - Extraglottic airway
c. Casualty with airway obstruction or impending airway obstruction:
   - Allow a conscious casualty to assume any position that best protects the airway, to include sitting up and/or leaning forward.
   - Use a chin lift or jaw thrust maneuver
   - Use suction if available and appropriate
   - Nasopharyngeal airway or
   - Extraglottic airway (if the casualty is unconscious)
   - Place an unconscious casualty in the recovery position
d. If the previous measures are unsuccessful, perform a surgical cricothyroidotomy using one of the following:
   - Bougie-aided open surgical technique using a flanged and cuffed airway cannula of less than 10 mm outer diameter, 6-7 mm internal diameter, and 5-8 cm of intratracheal length.
   - Standard open surgical technique using a flanged and cuffed airway cannula of less than 10mm outer diameter, 6-7 mm internal diameter, and 5-8 cm of intra-tracheal length.
   - Use lidocaine if the casualty is conscious.
e. Cervical spine stabilization is not necessary for casualties who have sustained only penetrating trauma.
f. Monitor the hemoglobin oxygen saturation in casualties to help assess airway patency.
g. Always remember that the casualty's airway status may change over time and requires frequent reassessment.

Airway Notes:
- If an extraglottic airway with an air-filled cuff is used, the cuff pressure must be monitored to avoid overpressurization, especially during TACEVAC on an aircraft with the accompanying pressure changes.

- Extraglottic airways will not be tolerated by a casualty who is not deeply unconscious. If an unconscious casualty without direct airway trauma needs an airway intervention, but does not tolerate an extraglottic airway, consider the use of a nasopharyngeal airway.
- For casualties with trauma to the face and mouth, or facial burns with suspected inhalation injury, nasopharyngeal airways and extraglottic airways may not suffice and a surgical cricothyroidotomy may be required.
- Surgical cricothyroidotomies should not be performed on unconscious casualties who have no direct airway trauma unless use of a nasopharyngeal airway and/or an extraglottic airway have been unsuccessful in opening the airway.

5. Respiration/Breathing

a. Assess for tension pneumothorax and treat, as necessary.
   - Suspect a tension pneumothorax and treat when a casualty has significant torso trauma or primary blast injury and one or more of the following:
     - Severe or progressive respiratory distress
     - Severe or progressive tachypnea
     - Absent or markedly decreased breath sounds on one side of the chest
     - Hemoglobin oxygen saturation < 90% on pulse oximetry
     - Shock
     - Traumatic cardiac arrest without obviously fatal wounds

     ❖ If not treated promptly, tension pneumothorax may progress from respiratory distress to shock and traumatic cardiac arrest.

   - Initial treatment of suspected tension pneumothorax:
     - If the casualty has a chest seal in place, burp or remove the chest seal.
     - Establish pulse oximetry monitoring.
     - Place the casualty in the supine or recovery position unless he or she is conscious and needs to sit up to help keep the airway clear as a result of maxillofacial trauma.
     - Decompress the chest on the side of the injury with a 14-gauge or a 10-gauge, 3.25-inch needle/catheter unit.
       - Either the 5th intercostal space (ICS) in the anterior axillary line (AAL) or the 2nd ICS in the mid-clavicular line (MCL) may be used for needle decompression (NDC.) If the anterior (MCL) site is used, do not insert the needle medial to the nipple line.
       - The needle/catheter unit should be inserted at an angle perpendicular to the chest wall and just over the top of the lower rib at the insertion site. Insert the needle/catheter unit all the way to the hub and hold it in place for 5-10 seconds to allow decompression to occur.
       - After the NDC has been performed, remove the needle and leave the catheter in place.

- If a casualty has significant torso trauma or primary blast injury and is in traumatic cardiac arrest (no pulse, no respirations, no response to painful stimuli, no other signs of life), decompress both sides of the chest before discontinuing treatment.

- The NDC should be considered successful if:
  - Respiratory distress improves, or
  - There is an obvious hissing sound as air escapes from the chest when NDC is performed (this may be difficult to appreciate in high-noise environments), or
  - Hemoglobin oxygen saturation increases to 90% or greater (note that this may take several minutes and may not happen at altitude), or
  - A casualty with no vital signs has return of consciousness and/or radial pulse.
- If the initial NDC fails to improve the casualty's signs/symptoms from the suspected tension pneumothorax:
  - Perform a second NDC on the same side of the chest at whichever of the two recommended sites was not previously used. Use a new needle/catheter unit for the second attempt.
  - Consider, based on the mechanism of injury and physical findings whether decompression of the opposite side of the chest may be needed.
  - Continue to re-assess!
- If the initial NDC was successful, but symptoms later recur:
  - Perform another NDC at the same site that was used previously. Use a new needle/catheter unit for the repeat NDC
  - Continue to re-assess!
- If the second NDC is also not successful: continue on to the Circulation section of the TCCC Guidelines.

b. All open and/or sucking chest wounds should be treated by immediately applying a vented chest seal to cover the defect. If a vented chest seal is not available, use a non-vented chest seal. Monitor the casualty for the potential development of a subsequent tension pneumothorax. If the casualty develops increasing hypoxia, respiratory distress, or hypotension and a tension pneumothorax is suspected, treat by burping or removing the dressing or by needle decompression.
c. Initiate pulse oximetry. All individuals with moderate/severe TBI should be monitored with pulse oximetry. Readings may be misleading in the settings of shock or marked hypothermia.
d. Casualties with moderate/severe TBI should be given supplemental oxygen when available to maintain an oxygen saturation > 90%.

6. Circulation

a. Bleeding
- A pelvic binder should be applied for cases of suspected pelvic fracture:
  - Severe blunt force or blast injury with one or more of the following indications:
    - Pelvic pain
    - Any major lower limb amputation or near amputation
    - Physical exam findings suggestive of a pelvic fracture
    - Unconsciousness
    - Shock
- Reassess prior tourniquet application. Expose the wound and determine if a tourniquet is needed. If it is needed, replace any limb tourniquet placed over the uniform with one applied directly to the skin 2-3 inches above the bleeding site. Ensure that bleeding is stopped. If there is no traumatic amputation, a distal pulse should be checked. If bleeding persists or a distal pulse is still present, consider additional tightening of the tourniquet or the use of a second tourniquet side-by-side with the first to eliminate both bleeding and the distal pulse. If the reassessment determines that the prior tourniquet was not needed, then remove the tourniquet and note time of removal on the TCCC Casualty Card.
- Limb tourniquets and junctional tourniquets should be converted to hemostatic or pressure dressings as soon as possible if three criteria are met: the casualty is not in shock; it is possible to monitor the wound closely for bleeding; and the tourniquet is not being used to control bleeding from an amputated extremity. Every effort should be made to convert tourniquets in less than 2 hours if bleeding can be controlled with other means. Do not remove a tourniquet that has been in place more than 6 hours unless close monitoring and lab capability are available.
- Expose and clearly mark all tourniquets with the time of tourniquet application. Note tourniquets applied and time of application; time of re-application; time of conversion; and time of removal on the TCCC Casualty Card. Use a permanent marker to mark on the tourniquet and the casualty card.

b. Assess for hemorrhagic shock (altered mental status in the absence of brain injury and/or weak or absent radial pulse).

c. IV/IO Access
- Intravenous (IV) or intraosseous (IO) access is indicated if the casualty is in hemorrhagic shock or at significant risk of shock (and may therefore need fluid resuscitation), or if the casualty needs medications, but cannot take them by mouth.
  - An 18-gauge IV or saline lock is preferred.
  - If vascular access is needed but not quickly obtainable via the IV route, use the IO route.

d. Tranexamic Acid (TXA)
- If a casualty will likely need a blood transfusion (for example: presents with hemorrhagic shock, one or more major amputations, penetrating torso trauma, or evidence of severe bleeding)
  OR
- If the casualty has signs or symptoms of significant TBI or has altered metal status associated with blast injury or blunt trauma:
  - Administer 2 gm of tranexamic acid via slow IV or IO push as soon as possible but NOT later than 3 hours after injury.

e. Fluid Resuscitation
- Assess for hemorrhagic shock (altered mental status in the absence of brain injury and/or weak or absent radial pulse.
- The resuscitation fluids of choice for casualties in hemorrhagic shock, listed from most to least preferred, are:
  (1) Cold stored low titer O whole blood
  (2) Pre-screened low titer O fresh whole blood
  (3) Plasma, red blood cells (RBCs) and platelets in a 1:1:1 ratio
  (4) Plasma and RBCs in a 1:1 ratio
  (5) Plasma or RBCs alone

  ❖ NOTE: Hypothermia prevention measures [Section 7] should be initiated while fluid resuscitation is being accomplished.

- If not in shock:
  - No IV fluids are immediately necessary.
  - Fluids by mouth are permissible if the casualty is conscious and can swallow.

- If in shock and blood products are available under an approved command or theater blood product administration protocol:
  - Resuscitate with cold stored low titer O whole blood, or, if not available
  - Pre-screened low titer O fresh whole blood, or, if not available
  - Plasma, RBCs, and platelets in a 1:1:1 ratio, or, if not available
  - Plasma and RBCs in a 1:1 ratio, or, if not available
  - Reconstituted dried plasma, liquid plasma or thawed plasma alone or RBCs alone
  - Reassess the casualty after each unit. Continue resuscitation until a palpable radial pulse, improved mental status or systolic BP of 100 mmHg is present.
  - Discontinue fluid administration when one or more of the above end points has been achieved.

- If blood products are transfused, administer one gram of calcium (30 ml of 10% calcium gluconate or 10 ml of 10% calcium chloride) IV/IO after the first transfused product.

- Given increased risk for a potentially lethal hemolytic reaction, transfusion of unscreened group O fresh whole blood or type specific fresh whole blood should only be performed under appropriate medical direction by trained personnel.
- Transfusion should occur as soon as possible after life-threatening hemorrhage in order to keep the patient alive. If Rh negative blood products are not immediately available, Rh positive blood products should be used in hemorrhagic shock.
- If a casualty with an altered mental status due to suspected TBI has a weak or absent radial pulse, resuscitate as necessary to restore and maintain a normal radial pulse. If BP monitoring is available, maintain a target systolic BP between 100-110 mmHg.
- Reassess the casualty frequently to check for recurrence of shock. If shock recurs, re-check all external hemorrhage control measures to ensure that they are still effective and repeat the fluid resuscitation as outlined above.

f. Refractory Shock
   - If a casualty in shock is not responding to fluid resuscitation, consider untreated tension pneumothorax as a possible cause of refractory shock. Thoracic trauma, persistent respiratory distress, absent breath sounds, and hemoglobin oxygen saturation < 90% support this diagnosis. Treat as indicated with repeated NDC or finger thoracostomy/chest tube insertion at the 5th ICS in the AAL, according to the skills, experience, and authorizations of the treating medical provider. Note that if finger thoracostomy is used, it may not remain patent and finger decompression through the incision may have to be repeated. Consider decompressing the opposite side of the chest if indicated based on the mechanism of injury and physical findings.

7. Hypothermia Prevention

a. Take early and aggressive steps to prevent further body heat loss and add external heat when possible for both trauma and severely burned casualties.
b. Minimize casualty's exposure to cold ground, wind and air temperatures. Place insulation material between the casualty and any cold surface as soon as possible. Keep protective gear on or with the casualty if feasible.
c. Replace wet clothing with dry clothing, if possible, and protect from further heat loss.
d. Place an active heating blanket on the casualty's anterior torso and under the arms in the axillae (to prevent burns, do not place any active heating source directly on the skin or wrap around the torso).
e. Enclose the casualty with the exterior impermeable enclosure bag.

f. As soon as possible, upgrade hypothermia enclosure system to a well-insulated enclosure system using a hooded sleeping bag or other readily available insulation inside the enclosure bag/external vapor barrier shell.
g. Pre-stage an insulated hypothermia enclosure system with external active heating for transition from the non-insulated hypothermia enclosure systems; seek to improve upon existing enclosure system when possible.
h. Use a battery-powered warming device to deliver IV/IO resuscitation fluids, in accordance with current CoTCCC guidelines, at flow rate up to 150 ml/min with a 38°C output temperature.
i. Protect the casualty from exposure to wind and precipitation on any evacuation platform.

8. Penetrating Eye Trauma

- If a penetrating eye injury is noted or suspected:
  - Perform a rapid field test of visual acuity and document findings.
  - Cover the eye with a rigid eye shield (NOT a pressure patch).
  - Ensure that the 400 mg moxifloxacin tablet in the Combat Wound Medication Pack (CWMP) is taken if possible and that IV/IO/IM antibiotics are given as outlined below if oral moxifloxacin cannot be taken.

9. Monitoring

- Initiate advanced electronic monitoring if indicated and if monitoring equipment is available.

10. Analgesia

a. TCCC non-medical first responders should provide analgesia on the battlefield achieved by using:
   - Mild to Moderate Pain
   - Casualty is still able to fight
     - TCCC Combat Wound Medication Pack (CWMP)
       - Acetaminophen – 500 mg tablet, 2 PO every 8 hours
       - Meloxicam – 15 mg PO once a day

b. TCCC Medical Personnel*:*

   Option 1
   - Mild to Moderate Pain
   - Casualty is still able to fight
     - TCCC Combat Wound Medication Pack (CWMP)
       - Acetaminophen – 500 mg tablet, 2 PO every 8 hours
       - Meloxicam – 15 mg PO once a day

Option 2

- Mild to Moderate Pain
- Casualty IS NOT in shock or respiratory distress AND Casualty IS NOT at significant risk of developing either condition.
  - Oral transmucosal fentanyl citrate (OTFC) 800 µg
    - May repeat once more after 15 minutes if pain uncontrolled by first

TCCC Combat Paramedics or Providers:

- Fentanyl 50 mcg IV/IO 0.5-1 mcg/kg
  - May repeat q 30 min
- Fentanyl 100 mcg IN
  - May repeat q 30 min

Option 3

- Moderate to Severe Pain
- Casualty IS in hemorrhagic shock or respiratory distress OR
- Casualty IS at significant risk of developing either condition:
  - Ketamine 20-30 mg (or 0.2 - 0.3 mg/kg) slow IV or IO push
    - Repeat doses q 20min prn for IV or IO
    - End points: Control of pain or development of nystagmus (rhythmic back-and-forth movement of the eyes).
  - Ketamine 50-100 mg (or 0.5-1 mg/kg) IM or IN
    - Repeat doses q20-30 min prn for IM or IN

Option 4

TCCC Combat Paramedics or Providers:

- *Sedation required:* significant severe injuries requiring dissociation for patient safety or mission success or when a casualty requires an invasive procedure; must be prepared to secure the airway:

  - Ketamine 1-2 mg/kg slow IV/IO push initial dose
    - Endpoints: procedural (dissociative) anesthesia
  - Ketamine 300 mg IM (or 2-3 mg/kg IM) initial dose
    - Endpoints: procedural (dissociative) anesthesia

  ❖ If an emergence phenomenon occurs, consider giving 0.5-2 mg IV/IO midazolam.
  ❖ If continued dissociation is required, move to the Prolonged Casualty Care (PCC) analgesia and sedation guidelines.

- If longer duration analgesia is required:

  - Ketamine slow IV/IO infusion 0.3 mg/kg in 100 ml 0.9% sodium chloride over 5-15 minutes.

- Repeat doses q45min prn for IV or IO
- End points: Control of pain or development of nystagmus (rhythmic back-and-forth movement of the eyes).

c. Analgesia and sedation notes:
    - Casualties need to be disarmed after being given OTFC, IV/IO fentanyl, ketamine, or midazolam.
    - The goal of analgesia is to reduce pain to a tolerable level while still protecting their airway and mentation.
    - The goal of sedation is to stop awareness of painful procedures.
    - Document a mental status exam using the AVPU method prior to administering opioids or ketamine.
    - For all casualties given opioids, ketamine or benzodiazepines – monitor airway, breathing, and circulation closely.
    - Directions for administering OTFC:
        - Place lozenge between the cheek and the gum.
        - Do not chew the lozenge.
        - Recommend taping lozenge-on-a-stick to casualty's finger as an added safety measure OR utilizing a safety pin and rubber band to attach the lozenge (under tension) to the patient's uniform or plate carrier.
        - Reassess in 15 minutes.
        - Add second lozenge, in other cheek, as necessary to control severe pain.
        - Monitor for respiratory depression.
    - Ketamine comes in different concentrations; the higher concentration option (100 mg/ml) is recommended when using IN dosing route to minimize the volume administered intranasally.
    - Naloxone (0.4 mg IV/IO/IM/IN) should be available when using opioid analgesics.
    - TBI and/or eye injury does not preclude the use of ketamine. However, use caution with OTFC, IV/IO fentanyl, ketamine, or midazolam in TBI patients as this may make it difficult to perform a neurologic exam or determine if the casualty is decompensating.
    - Ketamine may be a useful adjunct to reduce the amount of opioids required to provide effective pain relief. It is safe to give ketamine to a casualty who has previously received a narcotic. IV Ketamine should be given over 1 minute.
    - If respirations are reduced after using opioids or ketamine, reposition the casualty into a "sniffing position". If that fails, provide ventilatory support with a bag-valve-mask or mouth-to-mask ventilations.
    - Ondansetron, 4 mg Orally Dissolving Tablet (ODT)/IV/IO/IM, every 8 hours as needed for nausea or vomiting. Each 8-hour dose can be repeated once after 15 minutes if nausea and vomiting are not improved. Do not give more than 8 mg in any 8-hour interval. Oral ondansetron is NOT an acceptable alternative to the ODT formulation.

- The use routine of benzodiazepines such as midazolam is NOT recommended for analgesia. When performing procedural sedation, benzodiazepines may also be considered to treat behavioral disturbances or unpleasant (emergence) reactions. Benzodiazepines should not be used prophylactically and are not commonly needed when the correct pain or sedation dose of ketamine is used.
- Polypharmacy is not recommended; benzodiazepines should NOT be used in conjunction with opioid analgesia.
- If a casualty appears to be partially dissociated, it is safer to administer more ketamine than to use a benzodiazepine.

11. Antibiotics

a. Antibiotics recommended for all open combat wounds.
b. If able to take PO meds:
    - Moxifloxacin (from the CWMP), 400 mg PO once a day.
c. If unable to take PO meds (shock, unconsciousness):
    - Ertapenem, 1 gm IV/IO/IM once a day.

12. Inspect and dress known wounds.

a. Inspect and dress known wounds.
b. Abdominal evisceration – [Control bleeding]; rinse with clean (and warm if possible) fluid to reduce gross contamination. Hemorrhage control – apply combat gauze or CoTCCC recommended hemostatic dressing to uncontrolled bleeding. Cover exposed bowel with a moist, sterile dressing or sterile water-impermeable covering.
    - Reduction: do not attempt if there is evidence of ruptured bowel (gastric/intestinal fluid or stool leakage) or active bleeding.
    - If no evidence of bowel leakage and hemorrhage is visibly controlled, a single brief attempt (<60 seconds) may be made to replace/reduce the eviscerated abdominal contents.
    - If unable to reduce; cover the eviscerated organs with water impermeable non-adhesive material (transparent preferred to allow ability to re-assess for ongoing bleeding); examples include a bowel bag, IV bag, clear food wrap, etc. and secure the impermeable dressing to the patient using adhesive dressing (examples: ioban, chest seal).
    - Do NOT FORCE contents back into abdomen or actively bleeding viscera.
    - The patient should remain NPO.

13. Check for additional wounds.

14. Burns.

a. Assess and treat as a trauma casualty with burns and not burn casualty with injuries.
b. Facial burns, especially those that occur in closed spaces, may be associated with inhalation injury. Aggressively monitor airway status and oxygen saturation in such

patients and consider early surgical airway for respiratory distress or oxygen desaturation.

c. Estimate total body surface area (TBSA) burned to the nearest 10% using the Rule of Nines.
d. Cover the burn area with dry, sterile dressings. For extensive burns (>20%), consider placing the casualty in the Heat-Reflective Shell or Blizzard Survival Blanket from the Hypothermia Prevention Kit in order to both cover the burned areas and prevent hypothermia.
e. Fluid resuscitation (USAISR Rule of Ten):
    - If burns are greater than 20% of TBSA, fluid resuscitation should be initiated as soon as IV/IO access is established. Resuscitation should be initiated with Lactated Ringer's, normal saline, or Hextend. If Hextend is used, no more than 1000 ml should be given, followed by Lactated Ringer's or normal saline as needed.
    - Initial IV/IO fluid rate is calculated as %TBSA x 10 ml/hr for adults weighing 40- 80 kg.
    - For every 10 kg ABOVE 80 kg, increase initial rate by 100 ml/hr.
    - If hemorrhagic shock is also present, resuscitation for hemorrhagic shock takes precedence over resuscitation for burn shock. Administer IV/IO fluids per the TCCC Guidelines in Section (6).
    - Consider oral fluids for burns up to 30% TBSA if casualty is conscious and able to swallow.
f. Analgesia in accordance with the TCCC Guidelines in Section (10) may be administered to treat burn pain.
g. Prehospital antibiotic therapy is not indicated solely for burns, but antibiotics should be given per the TCCC guidelines in Section (11) if indicated to prevent infection in penetrating wounds.
h. All TCCC interventions can be performed on or through burned skin in a burn casualty.
i. Burn patients are particularly susceptible to hypothermia. Extra emphasis should be placed on barrier heat loss prevention methods.

15. Splint fractures and re-check pulses.

16. Cardiopulmonary resuscitation (CPR).

a. Resuscitation on the battlefield for victims of blast or penetrating trauma who have no pulse, no ventilations, and no other signs of life will not be successful and should not be attempted.
b. However, casualties with torso trauma or polytrauma who have no pulse or respirations during TFC should have bilateral needle decompression performed to ensure they do not have a tension pneumothorax prior to discontinuation of care. The procedure is the same as described in section (5a) above.

17. Communication.

a. Communicate with the casualty if possible. Encourage, reassure and explain care.
b. Communicate with tactical leadership as soon as possible and throughout casualty treatment as needed. Provide leadership with casualty status and evacuation requirements to assist with coordination of evacuation assets.
c. Communicate with the evacuation system (the Patient Evacuation Coordination Cell) to arrange for TACEVAC. Communicate with medical providers on the evacuation asset if possible and relay mechanism of injury, injuries sustained, signs/symptoms, and treatments rendered. Provide additional information as appropriate.

18. Documentation of Care.

- Document clinical assessments, treatments rendered, and changes in the casualty's status on a TCCC Card (DD Form 1380). Forward this information with the casualty to the next level of care.

19. Prepare for Evacuation.

a. Complete and secure the TCCC Card (DD 1380) to the casualty.
b. Secure all loose ends of bandages and wraps.
c. Secure hypothermia prevention wraps/blankets/straps.
d. Secure litter straps as required. Consider additional padding for long evacuations.
e. Provide instructions to ambulatory patients as needed.
f. Stage casualties for evacuation in accordance with unit standard operating procedures.
g. Maintain security at the evacuation point in accordance with unit standard operating procedures.

Principles of Tactical Evacuation Care (TACEVAC)

* The term "Tactical Evacuation" includes both Casualty Evacuation (CASEVAC) and Medical Evacuation (MEDEVAC) as defined in Joint Publication 4-02.

Basic Management Plan for Tactical Evacuation Care

1. **Transition of Care**
    a. Tactical force personnel should establish evacuation point security and stage casualties for evacuation.
    b. Tactical force personnel or the medic should communicate patient information and status to TACEVAC personnel as clearly as possible. The minimum information communicated should include stable or unstable, injuries identified, and treatments rendered.
    c. TACEVAC personnel should stage casualties on evacuation platforms as required.
    d. Secure casualties in the evacuation platform in accordance with unit policies, platform configurations and safety requirements.
    e. TACEVAC medical personnel should re-assess casualties and re-evaluate all injuries and previous interventions.

2. **Massive Hemorrhage** (same as Tactical Field Care)

3. **Airway Management**

    Endotracheal intubation may be considered in lieu of cricothyroidotomy if trained.

4. **Respiration/Breathing**

    Most combat casualties do not require supplemental oxygen, but administration of oxygen may be of benefit for the following types of casualties:
    - Low oxygen saturation by pulse oximetry
    - Injuries associated with impaired oxygenation
    - Unconscious casualty
    - Casualty with TBI (maintain oxygen saturation > 90%
    - Casualty in shock
    - Casualty at altitude
    - Known or suspected smoke inhalation

5. **Circulation** (same as Tactical Field Care)

6. Traumatic Brain Injury

a. Casualties with moderate/severe TBI should be monitored for:
- Decreases in level of consciousness
- Pupillary dilation
- SBP should be >90 mmHg
- O2 sat > 90
- Hypothermia
- End-tidal CO2 (If capnography is available, maintain between 35-40 mmHg)
- Penetrating head trauma (if present, administer antibiotics)
- Assume a spinal (neck) injury until cleared.

b. Unilateral pupillary dilation accompanied by a decreased level of consciousness may signify impending cerebral herniation; if these signs occur, take the following actions to decrease intracranial pressure:
- Administer 250 ml of 3 or 5% hypertonic saline IV/IO bolus.
- Elevate the casualty's head 30 degrees.
- Hyperventilate the casualty.
  - Respiratory rate 20
  - Capnography should be used to maintain the end-tidal CO2 between 30-35 mmHg.
  - The highest oxygen concentration (FIO2) possible should be used for hyperventilation.
  - Do not hyperventilate the casualty unless signs of impending herniation are present. Casualties may be hyperventilated with oxygen using the bag-valve-mask technique.

7. Hypothermia Prevention (same as Tactical Field Care)

8. Penetrating Eye Trauma (same as Tactical Field Care)

9. Monitoring (same as Tactical Field Care)

10. Analgesia (same as Tactical Field Care)

11. Antibiotics (same as Tactical Field Care)

12. Inspect and dress known wounds (same as Tactical Field Care)

13. Check for additional wounds. (same as Tactical Field Care)

14. Burns (same as Tactical Field Care)

15. Splint fractures and re-check pulses (same as Tactical Field Care)

16. Cardiopulmonary resuscitation (CPR) in TACEVAC

a. Casualties with torso trauma or polytrauma who have no pulse or respirations during TACEVAC should have bilateral needle decompression performed to ensure they do not have a tension pneumothorax. The procedure is the same as described in Section (4a) above.
b. CPR may be attempted during this phase of care if the casualty does not have obviously fatal wounds and will be arriving at a facility with a surgical capability within a short period of time. CPR should not be done at the expense of compromising the mission or denying lifesaving care to other casualties.

17. Communication

a. Communicate with the casualty if possible. Encourage, reassure and explain care.
b. Communicate with medical providers at the next level of care as feasible and relay mechanism of injury, injuries sustained, signs/symptoms, and treatments rendered. Provide additional information as appropriate

18. Documentation of Care (same as Tactical Field Care)

Committee on Tactical Combat Casualty Care (CoTCCC) in 2021.

SUMMARY OF 2021 CHANGES:

3. Massive Hemorrhage
    b. "CoTCCC-Recommended" is removed from junctional tourniquets. No specific products are recommended by the CoTCCC. End users should select any FDA-approved device that is indicated for junctional hemorrhage control.

4. Airway Management
    d. Removes Cric-Key technique as preferred option for surgical cricothyroidotomy and remove "least desirable option" from the standard open surgical technique. Units and end users should use the technique they are best trained to execute.

    Airway Notes: Removes iGel as the preferred extraglottic airway. Units may still use iGel if mission are at high elevation or evacuation is at high altitudes.

6. Analgesia – adjust Ketamine IV/IO dosing to 20-30 mg (or 0.2 – 0.3 mg/kg)

12. Inspect and dress known wounds

    b. Adds the preference of cleaning abdominal evisceration with clean and warm water if possible; clarifies guidance on conditions to attempt reduction of abdominal contents; that patient should remain NPO and NOT be administered oral medicals (Combat Wound Medication pack) and removes prolonged care considerations (now covered in separate PCC guidelines).

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Traumatic Brain Injury Management and Basic Neurosurgery in the Deployed Environment

Guidelines and recommendations for the treatment and medical management of casualties with moderate to severe head injuries in an environment where personnel, resources and follow-on care are limited.

First Publication Date: 03 Mar 2005 | Publication Date: 15 Sep 2023 | Supersedes: 02 Mar 2017

SUMMARY OF CHANGES

1. Clarification of the use of the Military Acute Concussion Evaluation 2 (MACE2) for mild traumatic brain injury (mTBI).
2. Clarification of the use of hypertonic saline or normal saline during resuscitation.
3. Addition of the recommendation to use quantitative pupillometry for evaluation of pupillary reactivity.
4. Addition of recommendation for Ketamine as a sedative in severe TBI.
5. Addition of recommendation for tranexamic acid (TXA).
6. Addition of recommendations to consider placement of Brain Tissue Oxygen Monitor (PbtO2) and maintaining > 20mmHg.
7. Addition of recommendation for vascular imaging of penetrating brain injuries to rule out traumatic pseudoaneurysms.
8. Changed seizure prophylaxis for TBI to make Levetiracetam the preferred agent and dilantin a third line agent given the inability to obtain drug levels in austere environments. Added in Vimpat as a second line agent for seizure prophylaxis.
9. Addition of treatment algorithms for treating elevated intracranial pressure, decreased PbtO2, or both.

Traumatic Brain Injury (TBI) & Neurosurgery in the Deployed Environment

Published by the Joint Trauma System, the DoD Center of Excellence for Trauma

IMPROVED OUTCOMES REQUIRE:

Point of Injury Care

- TCCC for life threatening injuries
- Hypotensive → Blood or TXA (2gms ≤ 3 hrs post injury)
- Normotensive → NS/ 3% Hypertonic Saline
- GCS ≤ 8 → SBP ≥ 110
- SaO2 > 90% → PaCO2 35-40 mmHg→ $ETCO_2$ 30 mmHg

Care ≤ 5 Hours Post-Injury

Who

- Penetrating head trauma
- Open skull fracture
- All moderate & severe TBI
- Mild TBI w/persistent confusion

What

- Neurosurgeon
- Advanced imaging
- Required equipment
- Critical care

Scope of TBI Casualties

14%: Combat

23% - 30%: Prehospital

30% - 45%: Hospital

Classification

Mild	GCS 13 - 15
Moderate	GCS 9 - 12
Severe	GCS 3 – 8

Monitor

- ICP < 22 mmHg
- CPP 60-70 mmHg
- PbtO2 > 20 mmHg
- Quantitative pupillometry (NPi) < 3 concerning for increased ICP

Medical Management

- Maintain normothermia
- Increase head of bed: ↑ 30°-45°
- Gastric ulcer prophylaxis

Sedation

- Propofol 20-75 mcg/kg/min
- Ketamine 2mg/kg
- Intermittent narcotics

Antiepileptic Meds

- Keppra
- Vimpat
- Phenytoin

Intracranial Hypertension

- Hypertonic Saline (3%)
- Na+ 150-160 mmol/L
- Mannitol 1g/kg Bolus (avoid in hypovolemic /hemorrhagic shock)

METRICS

GOALS

- SBP >110 mmHg
- MAP > 60 mmHg
- SaO2 >93%
- PaCO2 35-40 mmHg at every role of care

INTERVENTIONS

- Seizure prophylaxis
- Abx for open skull fractures
- NO STEROIDS
- ICP monitor placed prior to transport
- Hourly documentation of ICP/CPP & ventriculostomy drainage

PURPOSE

These guidelines are not intended to supplant physician judgment. Rather, these guidelines are intended to provide a basic framework for those less experienced with the delivery of care in this setting to the brain injured patient, as well as to educate and provide insight to others on the delivery of care in a restrictive environment.

BACKGROUND

Traumatic brain injury (TBI) occurs in about one third of all trauma-related deaths in the United States and remains one of the most common causes of death on the modern battlefield.[1,2] The Committee on Surgical Combat Casualty Care (CoSCCC) published a Neurosurgical Capabilities Position Statement in Feb 2023 given the importance of this issue. Specific to the combat environment:

- Positive outcomes are achieved through point of injury care to prevent secondary brain injury (avoid hypoxia, avoid hypotension), rapid evacuation from the battlefield, early medical management, timely neurosurgical intervention, meticulous critical care, and dedicated rehabilitation.[3-9]
- Optimal outcomes for severe TBI (Glasgow Coma Score [GCS] </=8) in theatre require a neurosurgical capability defined as a neurosurgeon, advanced imaging, required surgical sets, required monitoring, and critical care.
- For conflicts in Afghanistan and Iraq, Department of Defense Trauma Registry (DoDTR) data demonstrate: [10,11]
    - 14% of casualties sustained a traumatic brain injury.[10]
    - TBI was the mechanism of death for 30% of prehospital deaths from 2001 to 2011 and 45% of hospital deaths from 2001 to 2009.[12]
    - From 2014 to 2021 Armed Forces Medical Examiner System (AFMES) data demonstrate TBI accounted for 23% of prehospital deaths and 30% of hospital deaths (Unpublished JTS-AFMES data).
    - Over 5,600 neurosurgical procedures were performed in-theater between 2002-2016.[12]
    - Casualties with a TBI and an indication for neurosurgical intervention were more likely to survive if they received surgery within 5 hours of injury.[9]
    - Neurosurgical interventions performed on the battlefield after penetrating injuries result in improved survival.[13]
- Severe TBI also occurs during routine and crisis contingency operations, both ground and maritime combat, with an associated mortality of 69.7%.
- The incidence of TBI after non-combat maritime mass casualty events such as collisions is 5.8%; during modern naval warfare when warships are attacked by missile strikes or other explosive devices, the incidence of severe TBI is 17.2%.[14]
- Some patients with severe closed and penetrating brain injury had favorable outcomes when treated in military medical treatment facilities (MTFs) and received timely and aggressive neurosurgical and neuro-critical care interventions.[2-5,9]

CLASSIFICATION

The classification of brain injury informs prognosis and care eligibility in the combat environment. Brain injury severity is classified according to their **GCS.**

Table 1. Glasgow Coma Score

GLASGOW COMA SCORE	EYE OPENING	BEST VERBAL EFFORT	BEST MOTOR EFFORT
1	None	None	Flaccid
2	To Pain	Nonspecific sounds	Decerebrates to pain
3	To verbal stimuli	Inappropriate words	Decorticates to pain
4	Spontaneous	Confused	Withdraws to pain
5	-	Oriented	Localizes to pain
6	-	-	Follows commands

- Mild: GCS 13-15
- Moderate: GCS 9-12
- Severe: GCS 3-8

Neurosurgical care capabilities are available at designated Role 3 facilities, Role 4 facilities and in pre-identified partner nation facilities.

ROLE 3 TRANSFER FOR NEUROSURGICAL EVALUATION & CARE

Neurosurgical care in a combat theater is a limited resource and often requires air transport to get patients to the closest neurosurgeon or even Computed Tomography (CT) for diagnosis and treatment. Both over- and under-utilization should be avoided.

COALITION CASUALTIES

- Coalition casualties may require transfer for formal evaluation with a CT scan and/or a neurosurgeon when they:
  - continue to have a GCS < 14 (mild TBI needs further evaluation in coalition casualties if the GCS does not return to GCS of 15).
  - are confused or have continued cognitive deficits.
- The MACE2 is validated for determining the presence of an mTBI and should be used as an initial screening tool for to evaluate mTBI. It should not be used to determine worsening intracranial injury.[15-17]
- All coalition casualties should be referred for neurosurgical evaluation if they have:
  - Penetrating brain injury
  - Open skull fracture
  - Moderate or severe brain injury
  - Head trauma AND unexplained neurologic deficits

HOST NATION (HN) CASUALTIES

- Management of host nation casualties should be in accordance with medical rules of eligibility (MEDROE) established for the area of responsibility. TBI management and neurosurgical care of HN casualties are MEDROE dependent. Providers should care to the best of their capabilities for HN TBI patients and involve the theater Trauma Medical Director (TMD) and neurosurgery (NS) early in the management.
- When MEDROE permits, moderate brain injury in HN casualties should be referred to Role 3 facilities with neurosurgical capability for definitive care.
- All patients should ethically receive equal care; however, the realities of combat are that HN casualties with severe brain injury have a poor prognosis when follow-on care is not available after discharge from the military MTF. The decision to transfer HN casualties with severe brain injury to Role 3 is based on mission, tactical situation, and resource availability and is ideally preceded by direct communication and discussion with the TMD and neurosurgeon.
- Depending on the severity of TBI, considerations for transfer of HN casualties to HN facilities after Role 3 MTF care can be complicated, multifactorial, and dependent on current MEDROEs. HN patients may not receive optimal care after leaving the military MTF, which adds to the complexity of decision-making for the care of these patients. For patients with severe TBI and poor prognosis, palliative care at the in-theatre MTF may be most appropriate. These decisions should be made in the context of TBI severity and the available continuum of care for the patient in their nation of origin. Discussions with the theater neurosurgeon, TMD, and command elements can aid in this difficult decision.

EARLY EVALUATION & TREATMENT

The initial management of the patient with brain trauma begins with addressing life-threatening injuries and resuscitation in accordance with Tactical Combat Casualty Care (TCCC) guidelines in the field for corpsmen and combat medics or Advanced Trauma Life Support (ATLS) providers.[18]

Initial severe TBI treatment:
- *3% NaCl 250cc over 15 min*
- *Antiepileptics (Keppra 1500mg IV loading dose)*
- *TXA 2gm (if ≤ 3 hours post-injury)*
- *Antibiotics if open skull fracture*

- **Simple physical interventions to implement early:**
  - Head of bed elevated to 30-45 degrees or reverse Trendelenburg (if in spinal precautions)
  - Keep head straight to avoid kinking of the internal jugular veins (to promote venous drainage)
  - Avoid tight cervical collars and tight circumferential endotracheal tube/tracheostomy tube ties
- **Imaging**: Patients with a suspected traumatic brain injury with altered mental status (GCS 12 or less) should have a non-contrast head CT as soon as possible. For penetrating head injuries, in addition to the non-contrast head CT study, a CT angiogram of the brain should also be obtained to evaluate for vascular injuries (e.g., pseudoaneurysms).
- **Blood products** are the **preferred resuscitative fluid for hypotension in all trauma patients**. Avoid Albumin and hydroxyethyl starches; albumin is associated with worse outcomes when used in TBI patients.[19,20]

- **Tranexamic acid:** All patients with evidence of moderate or severe TBI should be administered 2gm of TXA within 3hrs of injury; 2gm of TXA in TBI patients improves survival.[21,]
- **If severe TBI is suspected, antiepileptics (Keppra, 1500 mg loading dose) should be administered during the initial evaluation and within 30 minutes of arrival.**
- **For casualties with abnormal GCS who do not require resuscitation** for hypotension or major blood loss, use normal saline or 3% hypertonic saline for volume resuscitation. Both have shown equivalent outcomes in severe TBI. **Avoid hypotonic fluids (e.g., any IVF with Dextrose % in water [D5W]**).
- **For casualties with GCS ≤ 8**, manage hypotension by maintaining systolic blood pressure greater than 110 mmHg.[22] A **systolic blood pressure of less than 90mmHg is the single risk factor most highly associated with mortality in brain trauma**.[23,24]
- **End tidal CO_2 ($ETCO_2$)** should be monitored during prehospital care and continued after handoff to a surgical team. Normoventilation with a goal partial pressure of carbon dioxide **($PaCO_2$) of 35-40 mmHg should be maintained or $ETCO_2$ of 30 mmHg.**
- **Prophylactic hyperventilation is not recommended** as it decreases cerebral blood flow. It may be used as a temporizing measure to reduce intracranial pressure in the setting of suspected herniation until other therapies are employed to decrease intracranial pressure as the patient is on the way to the operating room.[25] Hyperventilation can be harmful. [22]
- **For penetrating brain injuries and open skull fractures, routine prophylactic antibiotics** are indicated.[26] Antibiotic recommendations for the first level of surgical care include either cefazolin 2gm IV every 6-8 hours or clindamycin 600mg IV every 8 hours. If a penetrating head injury appears grossly contaminated with organic debris, consider addition of metronidazole 500mg IV every 8-12 hours.[26]
- **For isolated closed head injuries**, routine prophylactic antibiotics are not indicated.
- **Hypoglycemia and hyperglycemia must be avoided. Monitor glucose** every 6 hours. The goal is to maintain glucose < 180 mg/dl and avoid hypoglycemia.[27] **D5W IVF** will **worsen cerebral edema**. **Do NOT use intravenously** to maintain euglycemia.
- **Steroids should be avoided in brain-injured patients** as they have not shown outcome benefit and increase mortality in patients with severe brain injury.[25,28]
- **A common strategy for management of hypoxemia** has been a goal of arterial oxygen saturation (SaO2) >90% and the partial pressure of oxygen in the arterial blood (PaO2) >60 mmHg.[24] However, in order to establish a safety buffer in the deployed setting often characterized by frequent patient handoffs and occasional equipment challenges, a **goal SaO2 of 93-95% and PaO2 >80mmHg**, is recommended. Particular attention to avoidance of hypoxemia during air transport is essential as human studies and animal models indicate hypoxia during aeromedical evacuation is common.[29,30]
- **Document serial neurological exam findings every hour**, including:
  - Glasgow Coma Score broken down by eyes, voice, motor scores. (See Table 1.)
  - Presence of gross focal neurologic signs and/or deficit.
  - Pupil size and reactivity. See below Figures 1 and 2.
  - When available, quantitative pupillometry should be assessed and documented to ensure accuracy and consistency of recordings.[31-33] Quantitative pupillometry and the neurologic pupillary index (NPi) allows objective and consistent assessment of pupillary reactivity to track

trends and determine if a patient's responsiveness is worsening. ICU nurses should be documenting these findings and they should be trended.

- NPi < 3.0 is concerning for an abnormal or sluggish pupil and therefore increased intracranial pressure. NPi should be documented and significant changes indicate the need to assess or empirically treat for increased intracranial pressure. If a neurosurgeon is not managing the patient; telehealth support to review NPi should be considered. (See Appendix D.)

Figure 2. Pupillometer in Use

MEDICAL MANAGEMENT

SEDATION

There is a delicate balance when sedating patients with TBI. When transferring casualties to a neurosurgical capability for initial assessment, avoid long-lasting sedation or paralysis as this impedes the ability to evaluate the patient. However, medication selection should not override the need to safely transport the casualty.

- Propofol can be used for sedation, but caution must be used to avoid hypotension.[25]
- Ketamine is also useful for sedation (and can also provide some analgesia) as it avoids the significant hypotension associated with propofol and there is evidence it lowers intracranial pressure (ICP).[34-40]
- When narcotics are utilized for pain management, intermittent narcotic doses are preferred over continuous infusion.
- Routine paralysis of TBI patients should be avoided. If paralytics are needed, vecuronium is preferred because it is readily available in the austere environment and does not require refrigeration. Bolus dosing is preferred over continuous infusion. The recommended initial dose is 0.08 to 0.1 mg/kg given as an intravenous bolus injection. Paralytics should only be used if the patient is appropriately sedated. In general, paralytics should only be used for high-risk transport.

INTRACRANIAL HYPERTENSION

Despite controversy on the use of invasive monitoring to measure ICP, treatment of known or suspected intracranial hypertension remains a cornerstone of therapy in patients with severe brain injury.[42]

Intracranial hypertension should be suspected based on certain clinical criteria if no CT scan or intracranial monitor is available. These criteria include:

- GCS Motor Score < 4
- Pupillary asymmetry
- Interval development of pupillary asymmetry ≥ 2mm
- Abnormal pupil reactivity
- Decrease of motor score by ≥ 1
- New motor deficit
- Hypertension with Bradycardia
- If an automated pupillometer is present, an NPi < 3 on one or both eyes is concerning for raised intracranial pressure.

If treatment for intracranial hypertension is indicated prior to arrival to a neurosurgical capability, initiate hyperosmotic therapy with one of the following:

1. **Hypertonic Saline**[42,43] (Appendix B)
   - 250ml bolus of 3% saline administered over 10-15 minutes or a 30cc bolus of 23.4% saline.
   - In a location with no neurosurgical capability for definitive treatment, infuse 3% saline at 50-100ml/hr for resuscitation with goal serum Na level of 150-160mmol/L. If in the rare circumstance, chronic hyponatremia is suspected, elevation of plasma sodium by 3-5mmol/L over 2-4 hours is recommended.
   - Place central venous access to administer hypertonic saline and vasoactive medications, particularly if it is anticipated to be needed long term. Subclavian veins are preferred, followed by femoral, and lastly internal jugular.
2. **Mannitol**

   Avoid Mannitol during the initial resuscitation period when ongoing bleeding has not been ruled out and in hypotensive casualties (or any casualty with the risk of bleeding).

   Consider using Mannitol only if there is no availability of hypertonic saline and there is a significant concern for imminent herniation as evidenced by signs of intracranial hypertension described above.
   - Mannitol 1g/kg bolus IV.[25]
   - Hypotension after mannitol administration must be predicted and avoided. Urine output should be replaced with isotonic fluids.
   - When treating patients with osmotic agents, monitor serum sodium at least every 6 hours.

ANTIEPILEPTIC MEDICATIONS AND SEIZURES

Seizures are common after severe brain trauma. **Administer seizure prophylaxis** to avoid the hemodynamic changes and increased cerebral metabolic activity caused by seizures. Seizure medications help prevent early post-traumatic seizures, but do not prevent all seizures. Up to 25% of patients with severe TBI will have seizures even with prophylactic treatment. Fifty percent of seizures may be non-convulsive in nature. Patients with subdural hematoma, neurosurgical procedure, or penetrating brain injury are at the highest risk of seizures. Post-traumatic seizures have been shown to increase morbidity and mortality after trauma.[44-47]

- **If severe TBI is suspected, seizure prophylaxis should be administered during the initial evaluation and within 30 minutes of arrival.**
  - **Preferred agent:** Levetiracetam (Keppra) 1500mg IV loading dose, followed by 1000mg IV BID
  - **Second line agent:** Lacosamide (Vimpat) 400mg IV loading dose, followed by 200mg IV q12hours.
  - Continue seizure prophylaxis for 7 days after a moderate or severe TBI.[25,48-52] (Appendix A)
  - Seizure medications should be continued past post-injury day seven if the patient had evidence of seizure activity.
  - Rapid assessment and treatment of seizures is important to prevent secondary neurologic insult. Use a rapid response EEG device (if available) to diagnose seizures accurately and quickly.[54-58]
- **Active Seizures**

  Lorazepam 1-2mg IV or Midazolam 5-10mg IV. Lorazepam is preferred. If no IV access, Midazolam IM is as effective as Lorazepam IV

OTHER PRECAUTIONS

- Maintain normothermia. Avoid and treat hyperthermia.
- Elevate head of bed to 30-45° or use reverse Trendelenburg position for suspected concomitant spine/spinal cord injuries.
- Gastric ulcer prevention with an IV PPI should be started within 12 hours of admission.
- Consider enteral nutrition according to Nutritional Support Using Enteral and Parenteral Methods.[59]

AEROMEDICAL EVACUATION CONSIDERATIONS

Coordinating care between sending and receiving physicians is of paramount importance during patient movement. Neurosurgeons should discuss all patients being transferred to Role 4 with the receiving neurosurgical team to ensure a common understanding of the patient and the risks and benefits of aeromedical evacuation. Casualties with severe TBI should be manifest with altitude restrictions and the cabin pressured to 5000ft. PaO2 and SaO2 should be closely monitored in flight given the risk of barometric changes in PaO2.

INTRACRANIAL PRESSURE

ICP monitoring is recommended during aeromedical evacuation for patients who would meet the requirements stated below in the surgical management section.[61]

If appropriate neurosurgical capability and bed capacity are available, observation in theater may be warranted for patients with borderline ICP measurements. Stresses of flight including vibration, temperature, noise, movement, light, hypoxia, and altitude have been shown to increase ICP.[62,63]

Delayed evacuation may improve outcomes in patients with ongoing resuscitation needs and intracranial hemorrhage or decreased GCS. Since most intubated patients require heavy sedation and often paralysis during transport, neurologic exam cannot be followed and a neurologic deterioration may not be detected for many hours. Some patients have suffered herniation during long range evacuation. For example, this has occurred with patients who have significant burns requiring resuscitation who have intracranial hemorrhage or cerebral edema.

Do not remove a functional ICP monitor in the immediate period prior to aeromedical evacuation. This provides information to the Critical Care Air Transport Team (CCATT) team that can direct in flight treatment. Furthermore, it offers a level of safety in terms of stable ICP in patients who may otherwise require sedation or not have a reliable neurological exam.

DRAINS

Do not remove drains in the immediate period prior to aeromedical evacuation due to the risk of bleeding.

PNEUMOCEPHALUS

The effect of increasing altitude on contained air within the body, including the cranium, will potentially result in expansion of pneumocephalus; this is particularly true for those who have not undergone a decompressive craniectomy prior to the flight.

All patients should be transported with head of bed elevation or reverse Trendelenberg at 30-45°. Typically U.S. Air Force doctrine is to load all patient's feet first into the aircraft.[62] In a patient with TBI, the **aeromedical transport physician may consider loading headfirst, to maintain head elevation during flight**.

DEEP VEIN THROMBOSIS PROPHYLAXIS

All patients should be started on mechanical Deep Vein Thrombosis (DVT) prophylaxis at a minimum using sequential compression devices on uninjured extremities.

All trauma patients who are non-ambulatory require DVT prophylaxis, including brain-injured casualties. Chemical DVT prophylaxis in all moderate to severe head injured patients with normal coagulation profile should be started once there is a documented stable head CT, ideally no later than 24 hours after injury.

Caution in starting DVT prophylaxis and discussion with neurosurgeon is recommended for the following conditions:

- Polytrauma with or at risk for coagulopathy.
- Have intracranial monitor/drain in place.

- Have one or more of the following TBI features that are "high risk" for progression according to the Norwood-Berne criteria:
  - Subdural hematoma (SDH) ≥ 8mm
  - Epidural hemorrhage ≥ 8mm
  - Largest single contusion ≥ 2cm
  - More than one contusion per lobe
  - Diffuse or scattered subarachnoid hemorrhage.
  - Diffuse or scattered intraventricular hemorrhage.

For these patients, chemical prophylaxis may be started 72 hours post-injury or as neurosurgeon recommends (reference) [64,65]

Enoxaparin 30mg subcutaneous BID (preferred) or subcutaneous heparin, 5000U TID may be used as chemoprophylaxis.[25,66-68]

MULTIMODALITY MONITORING OF HEAD INJURIES

Non-operative management of intracranial hemorrhage requires neurosurgical consultation, repeat imaging until CT scan is stable, and serial exams.

Surgical intervention may be indicated in the management of patients with severe brain injury. This includes operative care such as evacuation of space-occupying hematomas via craniectomy or craniotomy as well as placement of multimodal intracranial monitors.

INTRACRANIAL PRESSURE MONITORING

Management of **severe TBI patients** using information from ICP monitoring is recommended. Although long-term outcomes have not been shown to be improved with ICP monitoring, there is evidence that in-hospital and two-week post-injury mortality is improved.[22] Additionally, the military trauma system may require multiple patient movements and handoffs that decrease the ability to follow neurologic exams. Therefore, ICP monitoring may detect a deterioration that would normally be detected on serial neurologic exam in a stable ICU environment.

ICP monitoring should be considered in all salvageable patients with:

- Severe TBI and abnormal CT showing one or more of the following:
  - hematoma
  - contusion
  - edema
  - herniation
  - compressed basal cisterns.[25]
- Severe TBI and a normal CT if 2 or more of the following are noted:
  - Age >40
  - Unilateral or bilateral posturing
  - Systolic blood pressure <90 mm Hg.[25]

Additionally, a **low threshold for ICP monitoring** should be maintained in severe TBI patients with **any abnormal head CT and inability to follow serial neurologic exam** such as during other surgical interventions required early after injury, long-range evacuation of intubated patients, etc.

Options for ICP monitoring:[25]

- External ventricular drain (ventriculostomy tube)
- Parenchymal ICP monitors. Codman ICP monitors are the only intraparenchymal device with aeromedical certification approved for U.S. Air Force aircraft.

If using antibiotic impregnated ventriculostomy, then no IV prophylactic antibiotics required. Otherwise, Ancef 1gm IV TID may be prescribed while ventriculostomy is in place (neurosurgeon's discretion).
The goal ICP is <22 mmHg.[25]

CEREBRAL PERFUSION PRESSURE

Cerebral perfusion pressure is defined as: CPP = MAP-ICP. [22] The goal cerebral perfusion pressure (CPP) is between 60-70 mmHg when the autoregulator status of the patient is uncertain.

BRAIN TISSUE OXYGEN MONITORING

- Aeromedical evacuation may decrease continuous brain tissue oxygen (PbtO2).[33,69,70] There is evidence that the combined management of PbtO2 and ICP may improve outcomes of neurologic function in patients with severe TBI.
- Consider placement of a multi-modality intra-parenchymal catheter for monitoring of both PbtO2 and ICP
- PbtO2 should be maintained greater than 20mmHg.
- Strategies for managing PbtO2 and ICP are outlined in Appendix A under Treatment Paradigms Operative Care by Neurosurgery based on CT results: Evacuation of Hematoma.

INDICATIONS FOR NEUROSURGICAL INTERVENTION

EPIDURAL HEMATOMA

All epidural hematomas > 30cc should be surgically evacuated regardless of the patient's GCS.[25]

EDH <30cc and with less than 15mm thickness and less than 5mm midline shift with a GCS >8 without a focal deficit may be managed non-operatively with appropriate monitoring in the ICU setting. These patients should be urgently transported to an MTF with neurosurgical capability for monitoring in case they decompensate.

SUBDURAL HEMATOMA

Craniotomy for evacuation of an acute SDH with a thickness >10mm or midline shift > 5mm regardless of the patient's GCS.

Craniotomy for evacuation of acute SDH with a thickness <10mm and shift <5 mm is indicated when there is a decrease in GCS of 2 or more, worsening pupillary exam, and/or and ICP greater than 20mm Hg. [25]

TRAUMATIC PARENCHYMAL LESION

Craniotomy for evacuation of a hematoma is indicated in a patient with GCS of 6-8 with frontal or temporal contusions greater than 20 cc in volume with midline shift or at least 5mm and/or cisternal compression on CT. [25]

Craniotomy for evacuation of a hematoma is also indicated in patients with lesions greater than 50 cc in volume in a salvageable patient.

POSTERIOR FOSSA MASS LESION

Mass effect on non-contrast CT or with neurological dysfunction or deterioration due to the lesion should undergo operative intervention as soon as possible. [25]

TRAUMATIC ANEURYSMS

A high index of suspicion is required for penetrating injuries of the skull base or across known major vascular territories. All penetrating brain injuries should undergo a CT Angiogram or Digital Subtraction Angiogram to rule out or diagnose a traumatic aneurysm as soon as possible.[8]

DEBRIDEMENT

Removal of devitalized brain tissue is an option in penetrating head injuries and in select cases of open skull fractures.[71]

FOREIGN BODY REMOVAL

The routine pursuit of individual foreign bodies (e.g., bullets, metallic fragments, bone) within the brain may cause additional tissue damage and is generally not advisable but should be left to the discretion of the neurosurgeon. Removal of fragments from the sensory, motor, or language cortex may reduce the risk of posttraumatic epilepsy.[72]

DURAL MANAGEMENT

Primary dural closure or limited duroplasty should be done in extremely limited instances as cerebral edema can progress in both severe and penetrating traumatic brain injury. Commonly, duragen or other dural substitute should be used as an overlay in the vast majority of cases during a decompressive hemicraniectomy. Dura can be reconstructed with temporalis fascia or fascia lata if a dural substitute is not available.[71]

DECOMPRESSION

Surgical decompression, or craniectomy, should be strongly considered following penetrating combat brain trauma.[5,73,74]

The kinetics of combat trauma can be very different from that seen in the civilian setting. The muzzle velocities of military rifles are much higher than civilian handguns which may lead to cavitation and surrounding devitalized tissue. Additionally, blasts can create four to five different classes of injury to the brain and other organ systems complicating management.[75]

1. Primary blast injury: blast overpressure from pressure waves.
2. Secondary blast injury: penetrating fragmentation injuries.
3. Tertiary blast injury: displacement of the casualty or blast debris that falls on the casualty.
4. Quaternary blast injury: injury from the thermal effect or release of toxins from the blast.

During transport, interventions for intracranial hypertension are limited to medical management. Craniectomy and en route monitoring devices may facilitate earlier CCATT transport of patients out of theater, however **long-range evacuation is not a benign intervention** and may increase secondary brain injury. **In cases of elevated ICP or in the early postoperative period, patients may be better served by delayed evacuation if possible.**

SKULL FLAP MANAGEMENT

Options for U.S. and Coalition Patients:

1. Those who have penetrating brain trauma: Do not save or send the calvarium as alloplastic reconstruction techniques are used for these casualties.
2. Those who have blunt trauma: Consider abdominal subcutaneous implantation of the calvarial flap for later reconstruction if it can be done in a sterile fashion.

Options for Host Nation Patients:

1. Clean and replace.
2. Clean and replace with hinge craniectomy. This involves partial fixation of the superior aspect of the bone flap, allowing it to "hinge" outward to accommodate swelling.[76]
3. Craniectomy with potentially limited chances for cranioplasty in the future, depending on local rules of eligibility.
4. In some locations, low temperature tissue freezing may be possible to allow replacement at a later time.

EXPLORATORY BURR HOLES (if no neurosurgeon or CT scan is available)

Exploratory burr holes have limited practical utility. They should **only be performed by a neurosurgeon or after consultation with a neurosurgeon** if possible and at a location where CT scan is not available to better guide management. Refer to the CPG entitled Emergency Life-Saving Cranial Procedures by Non-Neurosurgeons in Deployed Setting for additional guidance.

ICP MONITORING AND SURGICAL INTERVENTION (for Host Nation Patients)

Decisions to place ICP monitors or operate on host nation nationals should consider the available resources in the host nation for long-term care and rehabilitation.

PERFORMANCE IMPROVEMENT MONITORING

POPULATION OF INTEREST

- All patients with a diagnosis of traumatic brain injury and an initial GCS of 3-8.
- All patients who receive a cranial procedure (ICP monitor, craniectomy, craniotomy).

INTENT (EXPECTED OUTCOMES)

- All patients in population of interest avoid hypotension and hypoxia: SBP never < 110 mmHg, MAP never < 60mmHg, SaO2 never < 93%.
- All patients in population of interest have $PaCO_2$ monitored at every role of care; PaCO2 should not be >40mmHg or <35mmHg.
- All patients in population of interest have a head CT performed within 4 hours of injury and surgical intervention (if necessary) within 5 hours of injury.
- All patients with a ventriculostomy have hourly documentation of ICP/CPP and ventriculostomy output.
- All patients in population of interest who are unable to be monitored clinically (e.g., unable to hold sedation for Q1 hour neuro exam) have an ICP monitor or ventriculostomy placed prior to transport out of theater.

PERFORMANCE/ADHERENCE METRICS

- Number and percentage of patients in the population of interest with lowest SBP<110 within first 3 days after injury.
- Number and percentage of patients in the population of interest with MAP<60 within first 3 days after injury.
- Number and percentage of patients in the population of interest with SaO2<93% within first 3 days after injury.
- Number and percentage of patients in population of interest who have $PaCO_2$ documented at every role of care (POI, POI MEDEVAC, Role 2-4, interfacility MEDEVAC).
- Number and percentage of patients in the population of interest who maintain $PaCO_2$=35-40mmHg.
- Number and percentage of patients who had a head CT performed within 4 hours of injury.
- Number and percentage of patients who had a craniectomy performed within 5 hours of injury.
- Number and percentage of patients with a ventriculostomy who had hourly documentation of ICP/CPP and ventriculostomy output.
- Number and percentage of patients in the population of interest unable to be monitored clinically (e.g., unable to hold sedation for Q1 hour neuro exam) who have an ICP monitor or ventriculostomy placed prior to transport out of theater.

INTENT (EXPECTED OUTCOMES)

- Keep SBP > 110 mmHg, MAP > 60mmHg and SaO2 > 93% to prevent secondary brain injury.
- Steroids are not used on head injury patients.
- Hourly documentation of ICP/CPP and ventriculostomy output documented in medical record.
- Patients in whom neurological status cannot be monitored clinically and patients with severe TBI will have ICP or ventriculostomy placed prior to transport out of theater.
- Head CT completed within 4 hours of injury for moderate and severe TBI (may require patient transfer for CT).
- When neurosurgical intervention is indicated, it is started within 5 hours from injury.
- Antibiotics will be administered to patients with open head injuries as referenced above (as outlined in Infection Prevention in Combat-related Injuries CPG).

PERFORMANCE/ADHERENCE MEASURES

- SBP >110 mmHg, MAP >60mmHg, and/or SaO2 >93% documented upon discharge.
- Steroids were not administered.
- Neurological assessment and documentation of ICP/CPP and ventriculostomy output were recorded hourly in the ICU with pupillary exams. If used data from quantitative pupillometer including NPi added to the medical record.
- Patients in whom neurological status cannot be monitored clinically, and patients with severe TBI had ICP or ventriculostomy placed prior to transport out of theater.
- Patients with moderate to severe TBI had head CT performed.
- Patients with open skull fractures received prophylactic antibiotics.
- Patients were started on DVT chemoprophylaxis or a specific reason for no prophylaxis was noted.
- Sodium goal for patient documented.
- Seizure prophylaxis started for all moderate to severe TBI patients.
- Normothermia maintained.

DATA SOURCE

- Patient Record
- DoDTR
- ICU flow sheet
- Neurologic assessment flow sheet

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Chief and the JTS PI Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance, and PI monitoring at the local level with this CPG.

APPENDIX A: GENERAL INDICATIONS

MONITORING & LABS	GENERAL INDICATIONS*
INTRACRANIAL PRESSURE (ICP)/ BRAIN TISSUE OXYGEN	Glasgow Coma Score of 3-8 with an abnormal CT scan (hematomas, contusions, edema, or compressed basal cisterns) or 2 or more of the following adverse features are present in a patient with severe head injury and a normal head CT scan: (Age > 40 years, Unilateral or bilateral motor posturing, systolic blood pressure < 90 mmHg).
ARTERIAL LINE	Any head trauma that requires tracheal intubation and/or for other medical indications.
CENTRAL VENOUS PRESSURE	When ICP or CPP management requires anything beyond simple measures and/or for other medical indications. Trendelenburg position will raise ICP. Line site of choice is subclavian, then femoral, lastly internal jugular
EXHALED CO2	Desirable when active measures are required to control ICP. Correlate to $PaC0_2$ initially/periodically.
NEUROIMAGING	Non-contrast head CT upon admission then within 24 hours after admission (or earlier to document stability of the bleed). Additional scans obtained as indicated (e.g. clinical deterioration). Penetrating head injuries should undergo CTA or DSA if available to evaluate for vascular injury.
LABS	ABG, CBC, Chem 10, TEG, PT, PTT, and INR at least q8 hrs during the acute phase.
GENERAL MANAGEMENT PRINCIPLES*	
PHILOSOPHY	▪ Maintain continuous communication between the care teams. ▪ Maintain the patient in a "hyperosmolar-but-euvolemic" state with adequate oxygen carrying capacity and a constant substrate delivery via adequate CPP of >60mm Hg. Unless a MAP Challenge shows intact cerebral autoregulation then CPP > 70 mmHg. ▪ Aggressively avoid hypotension, hypoxemia, fever (>99 F), hyponatremia and other CNS insults. ▪ The longer the ICP is elevated (> 22), and the MAP & CPP are low (< 60), and PbtO2 < 20 the worse the outcome! ▪ Brain injury is heterogeneous amongst patients and the process is dynamic: Treatment and management goals must be tailored accordingly
RESUSCITATION FLUID	Normal saline (0.9%) or 3% hypertonic saline.
MAINTENANCE FLUID	Normal saline (0.9%)
SEDATION	Propofol 1st choice up to 72 hours. Other short-acting agents (Fentanyl, Versed) upon discretion of SICU or neurosurgical staff. Typical ICU **Propofol sedation dose range: 20-75 mcg/kg/min**. **Ketamine can also be considered** with dosages of **2mg/kg boluses for persistent elevated ICP** and/or with a continuous infusion.
ULCER PROPHYLAXIS	All patients.
DVT PROPHYLAXIS	Recognize high DVT risk in traumatic brain injury patients. Sequential Compression Device (SCD) and DVT prophylaxis should be started as soon as possible after a stable CT scan and in consultation with the theater Neurosurgeon.

MONITORING & LABS	GENERAL INDICATIONS*
SEIZURE PROPHYLAXIS	▪ Prophylactic anti-epileptic treatment is required for all severe traumatic brain injuries for 7 days if no seizure activity is documented. Keppra is the best choice for initial seizure prophylaxis. Vimpat (lacosamide), followed by Phenytoin or Fosphenytoin are second and third-line agents respectively. Given the narrow therapeutic index, multiple drug-drug interactions, and inability to obtain serum levels at Role III Facilities, Phenytoin should be used as a last resort if there are continued observed seizures, or there is a high suspicion of non-convulsive status epilepticus. ▪ Loading doses of Keppra in 20mg/kg followed by 1000 mg BID. ▪ Vimpat loading dose of 400mg IV, followed by 200mg IV q12hrs. ▪ Phenytoin can be dosed as 20 mg/kg infused at <50 mg/min or Fosphenytoin 20 PE (Phenytoin equivalent)/kg infused at <150 PE/min. The daily dose thereafter is 300 mg Phenytoin or 300 PE Fosphenytoin q HS or may be divided TID. Levels should be checked if available 30min after the loading dose and corrected for serum albumin should be between 10-20μg/mL. Dosing should then be 100mg TID and levels maintained at 10-20μg/mL.
ACUTE SEIZURE TREATMENT	Treat acute seizure with Lorazepam 1-2 mg IV or Midazolam 5-10 mg IV. Lorazepam is preferred for IV control. If no IV access is available, Midazolam IM is as effective as Lorazepam IV.
ANTIBIOTICS	If using antibiotic impregnated ventriculostomy, then no IV prophylactic antibiotics required. Otherwise, Ancef 1 gm IV TID while ventriculostomy is in place (neurosurgeons' discretion). For all penetrating head trauma, use cefazolin (see 3, a. 6) above.
NURSING	Hourly neurologic assessments. Document ICP/CPP and ventriculostomy output. Notify physician of all pertinent changes.
STEROIDS	Steroids are not recommended for head or spine trauma and should not be used.
NUTRITION	Enteral feeding should be begun as soon as it is safe to do so. Avoid agitation/ ICP during nasal or oral tube placement. Full enteral nutritional goal ≤ 7 days.

GENERAL MANAGEMENT GOALS (Goals may be individualized / altered by faculty according to specific patient requirements)*			
NEUROLOGIC	ICP	< 22 mm Hg	See page 13.
	PbtO2	> 20	
	CPP	> 60 mm Hg	
HEMODYNAMIC	Mean BP	Maintain to avoid ↓BP	▪ Hypotension (SBP < 90mmHg) worsens mortality. ▪ Provide a rapid physiologic resuscitation
	CVP	> 5 mm Hg	
PULMONARY	Sp02%	> 93%	Aggressive avoidance of hypoxemia
	$PaCO_2$	35 – 40 mmHg in first 24 hrs/	Avoid routine hyperventilation
HEMATOLOGIC	INR	≤ 1.3	Fresh frozen plasma
	Platelets	≥ 100,000/mm^3	Platelets
	TEG	Normalized values	As indicated by results
METABOLIC	Glucose	> 80 < 150 mg/dl	Have low threshold for insulin drip; avoid D5W IVF
RENAL	Serum Osmolarity	> 280 & < 320 mOsm	See Sodium Disorders, the bottom table in this general table.
	Serum Sodium	> 138 & < 160 meq/L	

INTRACRANIAL PRESSURE MANAGEMENT*	
GENERAL MEASURES	Head in midline position, avoidance of tight cervical collars and tight circumferential ETT ties; elevate the head of the bed to 30 degrees. (Consider reverse Trendelenburg)

MONITORING & LABS	GENERAL INDICATIONS*	
SEDATION	Propofol 1st choice up to 72°. Other short-acting agents (Fentanyl, Versed) upon discretion of SICU or neurosurgical staff. Typical ICU **Propofol sedation dose range: 20-75 mcg/kg/min**. **Ketamine can also be considered if the patient is hypotensive** or propofol is causing significant hypotension. **Ketamine infusion dosage ranges are from 20mcg/kg/min up to 100mcg/kg/min with 2mg/kg boluses for ICP spikes.**	
TEMPERATURE	Aggressive temperature management. Consider cooling measures (Tylenol, cooling blanket) even for modest temperature elevations (>98.6° F).	
INTRACRANIAL DYNAMICS	▪ Treat sustained ICP elevations >22 ▪ Treat sustained PbtO2 readings < 20 ▪ Always consider an expanding mass lesion with ICP elevations refractory to therapy or NPi decreasing less than 3.0.	
TREATMENT PARADIGM FOR THE TRAUMATIC BRAIN INJURY PATIENT*[(75)]		
ICP Elevated Brain Not Hypoxic **ICP >22mmHg** **PbtO2 > 20mmHg**	Tier 1	▪ Maintain CPP 60-70mmHg. ▪ Increase analgesia to lower ICP. ▪ Increase sedation to lower ICP. ▪ Maintain $PaCO_2$ at the lower end of normal (35-38 mmHg) ▪ Hypertonic saline by intermittent bolus ▪ CSF Drainage by EVD
	Tier 2	▪ Neuromuscular paralysis ▪ Perform MAP Challenge to assess cerebral autoregulation if autoregulation is intact. ▪ Raise CPP by fluid boluses, vasopressors, or inotropes. ▪ Ketamine bolus of 2ml/kg
	Tier 3	Consider secondary decompressive craniectomy
ICP Normal Brain Hypoxic **ICP < 22mmHg** **PbtO2 < 20mmHg**	Tier 1	▪ Increase FiO2 to 100% for 10 minutes to ensure the monitor is working and the PbtO2 improves. If the monitor is working proceed with further steps. ▪ Maintain CPP 60-70mmHg. ▪ Increase CPP to a maximum of 70mmHg with fluids, vasopressors, and inotropes. ▪ Maintain $PaCO_2$ > 35mmHg. ▪ If $PaCO_2$ is already in target range increase PaO2 to 60mmHg
	Tier 2	▪ Ventilator management to increase PaO2 as high as 150mmHg. ▪ Decrease ICP to less than 20mmHg. ▪ Consider CSF drainage ▪ Increase sedation to improve mechanical ventilation. ▪ Neuromuscular paralysis ▪ Perform MAP challenge to assess if cerebral autoregulation is intact. ▪ If cerebral autoregulation is intact, raise CPP to increase $PbtO_2$. ▪ Maintain ICP greater than 70mmHg with vasopressors, inotropes, fluid boluses
	Tier 3	▪ Increase $PaCO_2$ to 45-50mmHg (avoid intracranial hypertension) ▪ Consider normobaric hyperoxia to a PaO_2 above 150mmHg. ▪ If PbtO2 remains < 20 with CPP/MAP optimization, consider transfusing 1 Unit PRBC's if Hgb < 9g/L
ICP Elevated Brain Hypoxic **ICP > 22mmHg** **PbtO2 < 20mmHg**	Tier 1	▪ Maintain CPP 60-70mmHg. ▪ Increase CPP to a maximum of 70mmHg with fluid vasopressor, inotropes. ▪ Increase analgesia ▪ Increase sedation ▪ Maintain $PaCO_2$ > 35mmHg. ▪ Hypertonic saline by intermittent bolus ▪ CSF drainage ▪ If PaO_2 already in the desired range further increase PaO_2 by increasing $PaCO_2$ to 60mmHg

MONITORING & LABS	GENERAL INDICATIONS*	
	Tier 2	▪ Ventilator Management to increase PaO2 as high as 150mmHg. ▪ Neuromuscular Paralysis ▪ Perform MAP Challenge and if cerebral autoregulation is intact increase CPP to 70mmHg with vasopressors, fluid boluses, or inotropes.
	Tier 3	▪ Consider secondary decompressive hemicraniectomy. ▪ Consider normobaric hyperoxia to a PaO2 above 150mmHg. ▪ Consider transfusion of 1U PRBC's if Hgb < 9g/L and CPP/MAP and PaO2 are optimized.

ACUTE CLINICAL DETERIORATION
(e.g., Acute mental status change, blown pupil or other obvious signs of cerebral herniation, new focal neurological symptoms, progressive and refractory ICP elevation)*

1. Verify oxygenation and ventilation	**UNCAL HERNIATION SYNDROME** ▪ Unilaterally dilating pupil ▪ Progression to fixed and dilated. ▪ Progressive impairment of consciousness → comatose ▪ Contralateral Babinski → contralateral weakness → bilateral decerebrate rigidity
2. Hyperventilate ($PaCO_2$ 30-35 mmHg) to temporize only not longer than 15 minutes	
3. Re-dose osmotic agent	
4. Call Neurosurgery	
5. Arrange for emergent CT scan	

GLASGOW COMA SCORE	EYE OPENING	BEST VERBAL EFFORT	BEST MOTOR EFFORT
1	None	None	Flaccid
2	To Pain	Nonspecific sounds	Decerebrates to pain
3	To verbal stimuli	Inappropriate words	Decorticates to pain
4	Spontaneous	Confused	Withdraws to pain
5	-	Oriented	Localizes to pain
6	-	-	Follows commands

COMMON SODIUM DISORDERS SEEN IN HEAD TRAUMA (Discuss therapy with staff prior to initiation.)

Disorder	Na+	Diagnostic clues	Treatment
SIADH	↓	Low SOsm, usually euvolemic, ↑ Uosm Low serum Uric acid level	Free water restriction, hypertonic saline if severe
Cerebral salt wasting	↓	SOsm may be nl, ↑ uop, signs of volume depletion & hemoconcentration, very high UNa Normal serum uric acid level	Volume replacement with NS or hypertonic saline. Oral sodium. Beware of rapid Na+ correction.
Mannitol use	↑	Polyuria, ↑ [Na^+] & SOsm	Hold Mannitol if SOsm > 329 mOsm / [Na+] > 159
Diabetes Insipidus	↑	Polyuria (>250cc/hr), ↑ [Na^+] & SOsm, USpGr <1.005	DDAVP 2-4 mcg SQ/IV BID as permitted by staff neurosurgeon

APPENDIX B: HYPERTONIC SALINE PROTOCOL

Hypertonic (3% saline) may be delivered via peripheral IV or intraosseous access.

1. Give 250cc 3% sodium chloride (NaCl) bolus IV (children 5 cc/kg) over 10–15 minutes.
2. Follow bolus with infusion of 3% NaCl at 50 cc/hour.
3. If awaiting transport; check serum Na+ levels every hour:
   - If Na < 150 mEq/L re-bolus 150 cc over 1 hour then resume previous rate
   - If Na 150–154, increase NaCl infusion 10 cc/hour.
   - If Na 155–160, continue infusion at current rate.
   - If Na >160, hold infusion, recheck in 1 hour.
4. Once Na is within the range- continue to follow the serum Na+ level every 6 hours
5. After cessation of 3% NaCl infusion, and there is no further concern for cerebral edema the Na Levels should be lowered gradually back to the normal range. Recommend decreasing Na by 5mEq/L each day until normal and continuing to monitor at regular intervals for 24hrs after cessation of hypertonic saline.
6. A 30cc Bolus of 23.4% NaCl can also be given over 10-15 minutes. Can be given as IV piggyback or as an IV push over 10-15 minutes by an experienced provider.

APPENDIX C: CLINICAL USE OF PUPILLOMETRY

PURPOSE

To provide guidelines for the use of automated pupillometer in critical care patients with intracranial injuries. This guideline incorporates recent literature defining threshold parameters of normal versus abnormal in order to clarify when nursing staff should contact the primary team for re-evaluation. These guidelines are not a substitute for clinical judgment, but rather an approved multidisciplinary approach to optimize this clinical tool to identify neurologic worsening early while avoiding unnecessary alarms for the primary team.

This guideline applies to all patients for whom there is an intracranial neurologic injury with risk of decompensation per primary team.

BACKGROUND

The pupillary light reflex (PLR) has long been a clinical sign used to prognosticate and monitor brain injured patients. This neuronal circuit transverses the mid-brain and localizes to optic nerve, and oculomotor nerve and also receives blood supply from both anterior and posterior circulation[1]. Thus, there is interest in using this circuit to both monitor for early brainstem compression from mass lesions,[2] and also to identify alterations in circulation from processes such as delayed cerebral ischemia post subarachnoid hemorrhage[3] or increased intracranial pressure[4,5]. A basic neurologic examination includes evaluating the PLR and reporting size and reactivity, however these measurements are very subjective and suffer from poor inter-rater reliability[6,7]. With the advent of automated pupillometry, objective measures of the PLR can be reliably obtained with very high inter-rater and inter-device reliability[8] in civilian[9] and military[10] populations.

Beyond pupil size and reactivity, multiple metrics (pupil minimum / maximum size, percentage change of pupil, latency, constriction velocity, maximum constriction velocity, dilatation velocity) can be gathered and compared to normative standards. A commonly employed device is the NPi-200 Pupillometer, manufactured by NeuroOptics (Laguna Hills, CA). This device, in addition to gathering the above data, compares the gathered data to established normal values to create a Neurologic Pupillary Index (NPi) score which ranges from 0-5. NPi values < 3.0 reflect an abnormal PLR[5]. The presence of a decreased constriction velocity (CV < 0.8 mm/s) is also strongly correlated (but independent) to an abnormal NPi as well as independently associated with elevated intracranial pressure[11]. Developing an understanding of NPi and CV may provide early insight to neurologic deterioration[12].

Because of the rather large anatomic localization of the PLR and the ability to monitor the reactivity of this network reliably and accurately, it has been hypothesized that PLR can be used clinically to follow patients at risk for neurologic decline as a component to a regular neurologic examination. NPi values have been correlated with intracranial pressure as well as mass lesions with brainstem / cranial nerve compression[2,11]. However, more importantly, there is now evidence that changes in the NPi preempts clinical decline.

- In a case series of patients with transtentorial herniation, PLR changes preceded neurologic deterioration by more than 7 hours in half of the subjects[13].
- In a cohort of 56 patients who were admitted to Neurologic Intensive Care Unit with subarachnoid hemorrhage, 7 of 12 patients who developed delayed cerebral ischemia had NPi changes with 71.4% of these changes occurring 8 hours prior to clinical deterioration[3].
- In a cohort of 134 patients who had intracranial pressure monitoring and were evaluated with serial pupillometry, those subjects with abnormal NPi (< 3.0) had significantly higher peak ICPs (19.6 vs 30.5 mmHg). On average, the transition to an abnormal NPi occurred 15.9 hours prior to peak ICP[5].

RECOMMENDATIONS

1. For all patients at risk for neurologic decline from progression of intracranial lesion (traumatic brain injury, intracranial hemorrhage, intracranial mass lesions, vasospasm, hydrocephalus, etc.) pupillometry should be included and recorded with scheduled nursing neurologic examination.

2. If patient's pupillometry values meet any one of the below criteria, the neurosurgeon should be called to evaluate:
   a. NPi drops from > 3 to < 3.
   b. NPi decreases from previous exam > 1.0.
   c. A new difference in NPi (left eye vs right eye) is >1.0.
3. If above thresholds met, then evaluation should include:
   a. Review of vitals, inputs/outputs, current medications/drips
   b. Repeat full neurologic examination (GCS, cranial nerves, language, visual fields, motor exam).
   c. Contact Neurosurgeon on call.
   d. If deemed appropriate by the Surgical Trauma Intensive Care Unit and Neurosurgery repeat CT head (discussion with Neurosurgery if CTA of head and/or neck also indicated).
   e. Review and readdresses goals of neuroprotective measures (intracranial pressure, cerebral perfusion pressure, temperature, serum sodium, etc.).

APPENDIX D: INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Telemedicine Guidance in the Deployed Setting

This CPG is intended to be used as a guide to educate users in the deployed environment about the benefits and limitations of telemedicine.

Lifesaving direct patient care takes priority over calling for help! Never leave the casualty to get help if the casualty's condition may worsen while you are absent. Consider having a teammate "make the call "while the primary medical provider is delivering patient care.

Illustration by Raymond Samonte

Teleconsultation has been demonstrated to enhance care quality, reduce lost duty time, optimize evacuation decisions, reduce evacuation costs, and improve casualty outcome.

PURPOSE

This Teleconsultation (TC) clinical practice guideline (CPG) is intended for use by deployed U.S. healthcare providers who are working in contingency settings outside of established Military Treatment Facilities (MTFs) and includes care of Military Working Dogs (MWDs). TC is a subset of Telemedicine (TM) or Virtual Health (VH). TM and VH are synonymous terms that refer to the overall delivery of healthcare using communications technology, usually directly to a patient with video visits. In contrast, local caregivers (LCs) who need guidance to best manage a casualty with available resources and within operational constraints use TC (sometime referred to as an eConsult) to obtain it from remote experts (REs) not physically present with the casualty. Care teams may use a variety of communications technologies to conduct TC including asynchronous solutions like text messaging, email, and web portals and synchronous solutions like chat, phone calls, and video teleconferencing. Importantly, any TM, including TC, is governed by U.S. privacy laws, including the Health Insurance Portability and Accountability Act (HIPAA).

Operational virtual health (OVH), which supports TC for deployed providers, is a collection of solutions (versus a single integrated technology platform) that have evolved over time and require specific

knowledge, skills, and abilities (KSAs) for most efficient and effective use. This CPG provides this information and will be updated as the OVH system continues to evolve.

This guideline focuses on TC instead of TM because most casualties are managed by a deployed medical provider or buddy aid and, given current OVH solutions, it is more consistently available in operational settings. It is a guideline and is not intended to define a standard of care. Every deployed healthcare professional (HCP) and/or local caregiver (LC) making use of this guideline is responsible for evaluating the appropriateness of applying it in the settings of any context.

When available and used appropriately, TC is a critical enabler of better casualty care. It has been demonstrated to enhance care quality, reduce lost duty time, optimize evacuation decisions, reduce evacuation costs, and improve casualty outcome[1-6] but it is NOT a substitution for the deployment of necessary medical support, resources, and evacuation capabilities.

If you are a clinician expert and wish to provide TC as a RE, please contact the OVH Program Manager at the Virtual Medical Center (VMC) by sending an email from a DoD user account to dod.advisor-office@health.mil. ADVISOR is ADvanced VIrtual Support for OpeRational Forces.

BACKGROUND

The U.S. Military has been testing telemedicine solutions for nearly 30 years.[7] It was not until 2017, however, that telemedicine was recognized as an operational requirement by the Special Operations community.[8] Although Joint- and Service-specific requirements for telemedicine remain undefined, it is clear from experience and research that OVH can enhance management of complex casualties in austere and operational environments.[3,6,9-11]

Importantly, OVH provides clinical expertise to the point of need. When caregivers managing casualties reach the limit of their KSAs, two options exist for ensuring a patient receives optimal care: evacuate or call for help. Calling for help has been identified as best practice when it is uncertain if a casualty needs evacuation or when evacuation is not possible. Using TC alters evacuation plans of local caregivers in more than half of cases[2,3,12] and saves the U.S. Military millions of dollars annually. More importantly, these consultations have improved the care provided to casualties while simultaneously enhancing the LC's KSAs through education during the consultation and the RE's through increased understanding of austere and operational contexts.[9]

TC's major limitation is that it requires network resources; if the network is not available, then it is not possible to conduct TC. Still many misperceptions about this limitation exist that need to be dispelled:

- TC is widely accessible and used daily in all environments without specialized communications equipment. It uses available technology: cellular, radio, satellite phone or computer via voice, text, email, internet web portals. Encryption may enhance security or protect patient information but is not a requirement for most medical applications (see below).[13]
- Synchronous voice using radio or phone call is sufficient for most consultations. Voice calls plus asynchronous file transfer (i.e. images) is a highly flexible and adaptable solution for delivering consultation in very austere locations.[14-15] Video TC is most beneficial when LCs require tele-mentoring assistance by a RE to complete a procedure (e.g., fasciotomy, external fixation).[16-17]
- TC is a skill set and a tool that requires training, practice, and a PACE plan (Primary, Alternate, Contingent and Emergent). A team training in TC is able to adapt to conditions on the ground and optimize care for their patient. Last TC use when recorded sets the stage for future

technologies like artificial intelligence and machine learning to produce decision support solutions that do not require network resources.

- Lastly TC takes more time than you think. Conveying information to a RE about the patient to ensure the RE has a clear understanding of the casualty's problems and the clinical questions the LC needs answered are not always straight forward. The efficiency of TC may be improved by following the best practices outlined in this CPG.

Many clinicians fear TC because of concerns about a RE who may be unfamiliar with local context may be critical of care rendered in the operational setting. While this is a valid concern, it has not born out in case reviews and after-action reports. Feedback collected from real-world and training calls about LC experience with REs has been overwhelmingly positive.[3] Remote military experts understand operational constraints and try hard to provide consultation in context to LCs who are often faced with nearly impossible challenges to overcome.

OPERATIONAL TELECONSULTATION BEST PRACTICES

Prepare - Plan and Train

Operational TC begins with the PREP mnemonic: Prepare through Planning and Training; recognize when to "make the call," execute the consultation, and problem solve challenges. Ultimately, the safety and quality of care is the responsibility of the local caregiver and therefore telemedical support in the area of engagement (AOE) requires preparation and a PACE (Primary, Alternate, Contingency, and Emergency) plan to be successful. If a local caregiver intends to have consultation available but is unable to reach a remote consultant through one communications method, alternate methods should already have been established and tested. Thus, PACE planning takes two forms, one about when to utilize telemedicine and one for how to use telemedicine. See example in Table 1. A detailed example is in Appendix A.

Table 1. PACE Planning.

Examples provided of general AOE conceptual care plan and telemedical technology plan.
Note: the telemedicine technology PACE plan supports the alternate and contingency patient care plans. Consider the power, network, and equipment items below to be independent plans that could be "mixed-and-matched" according to need and functioning. Thus, the primary power plan could support the alternate network and contingency equipment. The technology plan should build from most reliable to least reliable.

PACE Planning		
	Patient care plan	**Telemedicine Technology**
Primary	Use local assets; evacuate the patient; pre-position resources (i.e. if you expect to need a surgeon, have an OR and a surgeon available).	Power: electrical grid Network: fiber or cable internet Equipment: Dedicated telemedicine equipment (i.e. VTC exam station, camera, augmented reality device)
Alternate	Use established telemedicine relationship to support care-in-place or during evacuation	Power: solar cell battery network: 4G/LTE cellular network Equipment: cell phone/tablet +/- peripheral exam equipment
Contingency	Use ad hoc telemedicine relationships (i.e. "phone-a-friend") to support care-in-place or during evacuation	Power: gasoline generator Network: Satellite Equipment: laptop/desktop computer, digital camera, e-mail
Emergency	Use un-approved, non-standard local solutions (i.e. local economy, high-risk care by untrained individual) to achieve "best-possible" outcome	Power: batteries Network: telephone, radio Equipment: phone, radio

Once a plan exists for when and how to perform TC, medical teams must train in realistic scenarios that require TC use to ensure this capability is available and easily utilized when needed. Given a variety of constraints in time, Class VIII (medical material equipment, consumables, blood), funding, and personnel, most medical training focuses on managing common casualties in typical operating contexts. These scenarios rarely require LCs to engage in TC because the scenarios do not outstrip their level of training or resource availability. TC, in its current form, is an ALTERNATE care plan for prolonged casualty care (PCC) or unusual cases that exceed PRIMARY plans. Therefore, training must include unexpected scenarios that require KSAs that are unavailable to the trainees and cannot be reasonably obtained by them prior to a deployment or within their scope of practice, and thus require them to call for help from a RE. Examples include:

- Medics/corpsmen managing a burn patient over time, especially if needs include an escharotomy and advanced airway management.
- Role 1 providers managing severe community acquired pneumonia that requires mechanical ventilation or a patient with an extremity injury that requires fasciotomy.
- Role 2 surgical team managing a casualty with a head injury that requires neurosurgical input and a decompressive craniectomy or a septic patient that develops the acute respiratory distress syndrome.
- Role 3 team managing a local national with an infection caused by a highly drug resistant organism, or a patient with acute kidney injury that requires renal replacement therapy, or a burn patient with severe inhalation injury.

RECOGNIZE

Culturally, the U.S. Military trains medical providers to succeed on their own merits; we validate individuals, not their ability to perform tasks or manage casualties as teams. Consequently, one of the hardest aspects of TC is for LCs to recognize when they should call for help. When a healthcare provider is uncertain about a casualty's diagnosis or the best management plan, s/he should consider calling for help. Because there is no single-entry point for TC within the OVH system, LCs must first determine the urgency of the consultation and then conduct TC using the appropriate technology. The OVH system is divided into routine TC and urgent/emergent TC, and direct patient care. Table 2 on the next page highlights these TC pathways and when LCs should use one or the other.

Table 2. The operational virtual health system according to teleconsultation acuity and direct-to-patient telemedicine.

The caller must identify that they are requesting support for patients located in a garrison MTF.</td></tr>
</table>

Global Teleconsultation Portal (GTP) is a Defense Health Agency (DHA) supported low-bandwidth web-based, secure, HIPAA-compliant, asynchronous platform used for non-urgent provider-to-provider teleconsultation, patient movement, and case management. Operational providers and consultants can access GTP and request a new account at: https://help.nmcp.med.navy.mil/path/user/Login.jsp

Lifesaving direct patient care takes priority over calling for help! Never leave the casualty to get help if the casualty's condition may worsen while you are absent. Consider having a teammate "make the call "while the primary medical provider is delivering patient care.

EXECUTE

The hardest and most dangerous part of TC is for the RE to efficiently provide an accurate consultation when unable to assess a casualty themselves – inaccurate information can lead to bad recommendations and, in the worst case, bad patient outcomes, or, more commonly, confusion. Consequently, the hardest part of TC for the LC is conveying an accurate description of a patient to a RE.

LCs must possess excellent assessment skills and the ability to convey their assessment to a RE efficiently. Inaccurate and/or incomplete assessments poorly communicated to a RE makes TC inefficient because the RE will inevitably pose probing questions of the LC to better understand a casualty's condition, problems, and treatments.

To date, no adverse outcomes associated with military TC have been reported. More commonly, poorly communicated data or incomplete assessment leads to frustration, lengthy consultations, dissatisfaction with recommendations, and ultimately delayed casualty care.

To avoid this, LCs must be prepared for TC. Unfortunately, many caregivers may find conducting a TC to be anxiety provoking because they may be unsure of their assessment, uncertain about what information to provide an RE, and are worried the RE will judge them. Probing RE questions to gain further confidence in data shared may feel uncomfortable for LCs, especially if/when data is missing due to incomplete assessment. THIS IS COMMON: every caregiver has a different way of prioritizing information and not all information will be available at the time of consultation. Real world consultations take an average of three (3) synchronous TC encounters to complete, often with several asynchronous communications between synchronous touch points. Missing data may be filled in over-time and recommendations may be refined or even changed as information is updated.

The following best practice recommendations have been identified to maximize TC efficiency, information transfer, and quality of recommendations while minimizing frustration and risk of missing information necessary for best consultation in context:

1. If calling the ADVISOR line:
    - When the agent answers the phone, tell the agent if the call is real-world and deployed or in garrison or for training.
    - Indicate the specialty needed or, if unknown, ask for the emergency department.
    - Provide a good call-back number.
2. Use a script familiar to the both the local caregiver and remote consultant (see Appendix B for an example with an instruction on use).
3. Send background information using asynchronous technology ahead of synchronous TC encounters (see below).
4. Use closed loop communication that includes intentional pauses in communication for read-back and clarification.

5. Have the RE document the telemedicine encounter and send that documentation with a summary of recommendations to the LC using an agreed upon asynchronous solution.

Images and Asynchronous File Transfer - Best Practices

Sending information, documentation, files, and particularly images (sometime of other files) related to casualty care before synchronous TC is a best practice because it allows the RE to consider the context of the consultation and to begin organizing thoughts ahead of the TC.

1. Ideally, send images of patients and care context to REs before starting a TC. This helps the remote expert to provide "consultation in context" and avoids recommendations that are discordant with local capabilities. Useful images include:
    - Flowsheet and other documentation like the TC script
    - Patient wounds
    - Imaging – pictures or video of collected imaging studies (ultrasound, x-ray, etc.)
    - Whole patient
    - Special equipment
    - Facility or aid station
2. Image quality is important (Figure 1). Photographs that are less than 500KB are often of insufficient quality to convey information to a remote consultant.
3. Be mindful of patient privacy and operational security (OPSEC):
    - Images should be compliant with HIPAA. Do not include personally identifiable information in the image like full face images and unique tattoos unless they are essential for communicating injury or disease state to the remote expert in which case the image must be encrypted before sending. Best practice is to use the GTP to send these images.
    - Similarly, do not include images of the environment that could cause a safety issue for the local care team by exposing their location or affiliation or other information that could be used against them (consider, for example, media implications of the image).
4. Note that digital photos may also contain "geotags" which can provide an exact location where it was taken. This feature can be disabled if there are security concerns. The easiest way to do so is to disable location services on your device before taking pictures.

Security - Cyber, OPSEC

- DO NOT DELAY teleconsultation due to an unsecure connection unless operational requirements dictate otherwise.
- Traditional teleconsultation is UNCLASSIFIED; the local caregiver should maintain normal rules of operational security when utilizing unclassified networks. Most RE consultants DO NOT have access to SECRET communications, but this may be established in special circumstances after UNCLASSIFIED communication is established first.
- Maintaining patient privacy should be a priority, and many available tools for communication meet patient privacy requirements.
- When sending patient information or images by open communication methods, limit patient identification to gender and age. Location can be generic by addressing temperature (hot/warm/cold), surroundings (urban/rural), or environments (desert/tropical).

- Location to the level of continent or region can be useful for the consultant/expert to better identify diseases specific to certain areas (e.g., hemorrhagic fevers, malaria, etc.).

The provided examples in the above figure are examples of call scripts sent ahead of the teleconsultation (TC) with a remote expert (RE). Panel A (size 2.17MB) is larger, takes more time to send, but is of sufficient quality to be read. Panel B (size 36.4kb), transmits easily, but is uninterpretable and of no utility. A reasonable file size that balances transmissibility and legibility is 500-1000kb (0.5-1MB).

Panel C is a great example of legible and functional transmission of a vital sign flow sheet with the interventions sent to the RE prior to the initiation of TC.

PROBLEM SOLVE

A general understanding of the capabilities and limitations of the various TM and TC technologies available is important. Intentionally using different technologies during training, especially switching between them, and limiting network resources during an encounter, helps LCs and REs become flexible in their use of technology and its limitations for delivering casualty care with TC support. ***Not all questions can be answered with TC; sometimes the best recommendation is simply to evacuate the casualty or experience the consequences.*** Still, TC may help mitigate risks if/when evacuation is no possible or available quickly.

Synchronous video helps make TC more efficient because REs can see what is happening in real time, but it is rarely required if TC does not involve tele-mentoring a procedure. Preliminary data from a small study presented in abstract[10] demonstrates that key aspects of procedural quality may suffer when voice only TC is utilized for procedural tele-mentoring compared to video. When not performing a procedure, sending image asynchronously and/or providing detailed description by text or during synchronous audio TC can convey the same information as real-time video with significantly less network consumption. Indeed, some procedures can be completed with frequent asynchronous "chats" that include images (often with the RE sharing annotations on the image).

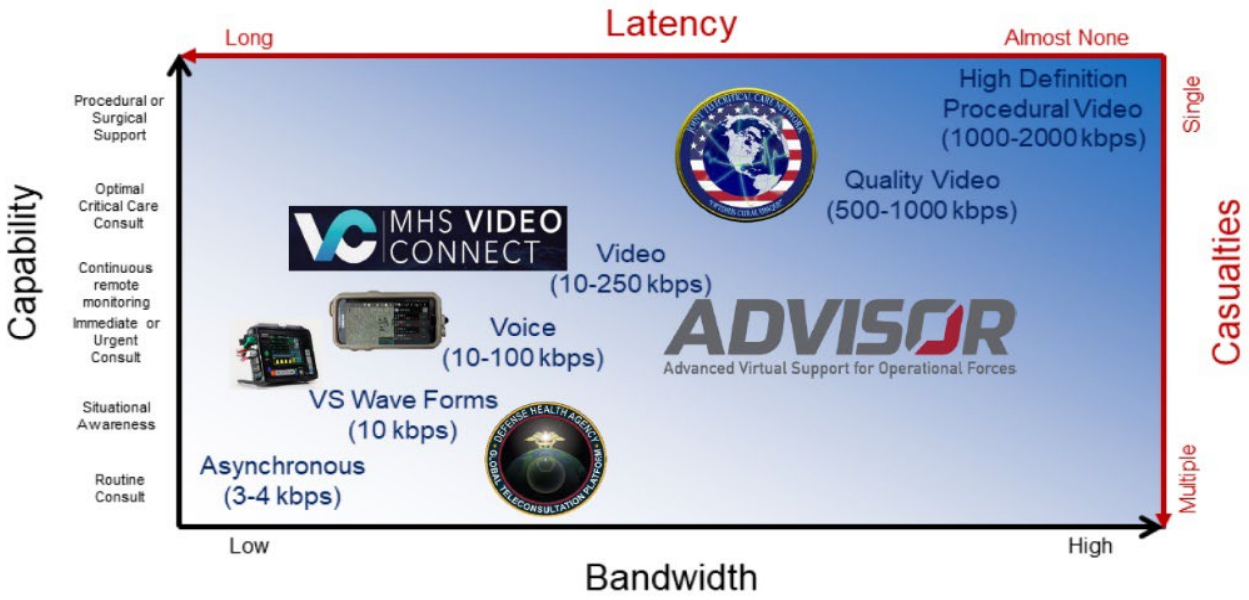
Because the telemedicine capability is a function of network resources matched to the number of casualties or encounters (Figure 2), understanding this relationship is important for mission planning.

Always use the most appropriate technology to optimize the consultation. Do not waste time establishing a network heavy video TC if lesser or more available technology (i.e. a radio or phone call) is sufficient. Also, it may be possible to increase the technology (i.e. go from an asynchronous consultation to a video consultation) if resources (hardware, software, and network) are available and the TC would benefit.

Understand the limitations of your technology and how to maximize its utility. It is difficult to complete a physical exam or part of a physical exam virtually without the correct digital equipment (e.g., stethoscope, ophthalmoscope, otoscope, etc.). Similarly, if bandwidth is limited, but video is needed by the RE for understanding, consider turning off the RE's video (thus decreasing bandwidth needs by approximately half).

If utilizing TC for casualty care, always have a back-up means of communication – a second radio/frequency, a second phone-line/cellphone (on both ends of the encounter – LC and RE), an alternate computer – whatever your pace plan states. At the beginning of an encounter, always ensure that call back numbers and second options are discussed at the beginning of the consultation (this is included in the example call scripts in Appendix B). Train to use back-up options.

Figure 2. Telemedicine capability is a function of network resources, particularly bandwidth and latency, matched to the number of casualties or encounters.



While network resources may be robust and able to support multiple continuous remote monitoring encounters, they may rapidly diminish when supporting a real-time, high quality video teleconference to facilitate a procedure. Similarly, asynchronous modes of communication (texting, email) require little bandwidth making it possible for many local caregivers to consult remote experts simultaneously, but it will take longer to receive responses. Increasingly synchronous and higher quality modes of communication require increased amounts of bandwidth but deliver shorter latent periods and increased capabilities to support local caregiver needs. Increasing network resources increased capability or encounter volume or both.

DOCUMENTATION

Documentation of the TC encounter is important for process improvement and lessons learned as teleconsultation continues to develop and inform future CPG development.

Documentation of casualty care is ultimately the responsibility of the LC providing direct care. All theater and local command documentation requirements should be completed by the LC. Best practice, however, is for REs to also document their consultation and recommendations and to send them to the LC as soon as possible. For routine consultations, this is automatic within the GTP. For TC not utilizing the GTP (urgent/emergent consultation), asynchronous communication between LCs and REs is on an ad hoc basis (using HIPAA compliant messaging applications or using encrypted email).

Additionally, REs document all OVH encounters using the Operational Virtual Health Report (OVHR) available at: https://info.health.mil/army/VMC/Lists/OperationalVirtualHealthReport/Item/newifs.aspx?source=/army/VMC/Pages/VMC/ADVISOR.aspx (must have CAC enabled computer/mobile device).

If a TC is for a casualty who is a Military Health System beneficiary, and at least two of the following patient identifiers are available and can be provided by the LC managing the casualty, REs should document the encounter in MHS Genesis or other electronic medical record:

- Patient name
- Social Security Number
- DoD Identification Number
- Date of Birth

Best practice is to copy information from the OVHR into the appropriate note in the EMR.

TC encounters for patients who are NOT MHS beneficiaries or for whom identifiers are not available/cannot be provided cannot have documentation in the EMR. REs will complete OVHRs and send recommendations to LCs as described above.

LCs utilizing ADVISOR for TC are also asked to complete an Operational Virtual Health Evaluation (OVHE) available at: https://info.health.mil/army/VMC/Lists/OperationalVirtualHealthEvaluation/Item/newifs.aspx?source=/army/VMC/Pages/VMC/ADVISOR.aspx .

When deployed LCs need to follow up with the appropriate medical theatre POCs on where they should document the patient encounter.

SUMMARY & KEY POINTS

While Joint requirements documents for OVH continue to process, military medical providers have increasingly utilized formal and informal OVH capabilities to solve real-world problems. This is a natural evolution of casualty care secondary to continuous improvements in communications technologies, the process of healthcare delivery learnt during medical training, and the specialization and sub-specialization of the medical profession that occurs with the march of scientific discovery in medicine.

This guideline has focused on TC as a tool for increasing LC's KSAs in real-time through care coordination with a RE, effectively increase scope of practice to manage complexities of casualty care created by operational constraints (like delayed evacuation). The CPG highlights the PREP mnemonic as a model for maximizing the benefit of TC and minimizing risks.

The following best practices for TC in resource limited, austere, and operational environments are summarized as follows:

1. **PREPARE:** Telemedicine is a skill that must be practiced by both local caregivers and remote experts to prepare for efficient and effective interactions. Ideally, this care team should train together using simulated patients to optimize their communication and ensure their technology choices match their clinical needs. Utilize PACE planning to harden your TC capabilities (Appendix A).
2. **RECOGNIZE:** Local caregivers must recognize when TC is necessary (i.e. "when to make the call") and what process to use based on the acuity of casualty. Conceptually, the more "acute" a

patient is, the earlier and more frequently the LC should engage with the remote expert. "Call early, call often" is a saying used often by REs when casualties are severely ill or injured. Routine, Urgent, and Emergent TC should be conducted using the resources outlines in Table 2.

3. **EXECUTE:** Effective and efficient teleconsultation takes practice, but can be improved by
   - Using a script familiar to the both the local caregiver and remote consultant (Appendix B).
   - Sending background information using asynchronous technology ahead of synchronous telemedicine encounters.
   - Using closed loop communication that includes intentional pauses in communication for read-back and clarification.
   - Having the remote expert document the telemedicine encounter and sending that documentation with a summary of recommendations to the local caregiver.
4. **PROBLEM SOLVE**: Understand the capabilities and limitations of available TC technologies and what types of TC can be performed using them. Be able and willing to switch between technologies when appropriate and have back-up communications solutions.

https://prolongedfieldcare.org/telemed-resources-for-us-mil/ offers some excellent information about operational TC form an experienced group of clinicians.

Additional information about the GTP and ADVISOR programs can be found at: https://info.health.mil/army/VMC/Pages/Home.aspx or by emailing dod.advisor-office@mail.mil

When utilized effectively, TC can improve casualty care, reduce evacuation costs, and optimize casualty outcomes in many challenging deployment contexts.

When in doubt, call early and call often.

PERFORMANCE IMPROVEMENT

JTS is a performance improvement (PI) organization which employs a systematic approach to determine the acute and long-term outcomes of all casualties, the quality of care, improvements in prevention and treatment and logistical implications. The JTS supports U.S. military PI initiatives by identifying, tracking, and making recommendations on PI measures to ensure the appropriate evaluation and treatment of injured Service members across the continuum of care and improve patient transition between phases of care.

The JTS PI Branch coordinates all PI activities across the spectrum of DoD trauma care and resolves trauma system patient care issues. JTS PI work relies on data collected in the DoD Trauma Registry. The data enables JTS to conduct gap analyses for medical capabilities to direct ongoing and future combat casualty care research, trauma skills training, and direct combat casualty care.

OVH utilizes encounter and summary statistics collected from the GTP, ADVISOR call center, OVHRs, and OVHEs to monitor the "health" of the system. Metrics tracked from these sources include:

- Number of Routine, Urgent, and Emergent TCs
- Location origin by Combatant Command

- Number of missed calls and failed connections
- Time from call to connection with RE (urgent/emergent calls) or time to receive recommendation form RE (routine)
- Quality of LC consultations (quality of presentation, appropriateness of questions, ability to provide appropriate recommendations)
- Quality of RE consultations (quality of the interaction, quality of the recommendations, and ability to implement recommendations
- Casualty outcomes when available
- Evacuations avoided or downgraded
- % of OVHR/OVHE completion

PI MONITORING

POPULATION OF INTEREST

Patients in resource-constrained operational environments requiring teleconsultation using the GTP and ADVISOR platforms.

INTENT (EXPECTED OUTCOMES)

- Local caregivers develop and maintain a teleconsultation PACE plan as part of mission planning.
- Local caregivers utilize call scripts when communicating with remote experts on ADVISOR.
- ADVISOR remote experts forward written guidance to local caregivers as a supplement to verbal advice.
- Teleconsultation details are documented with the encounter in the patient's health record. Details include consultant's name, specialty, and recommendations.
- Local caregivers submit an Operational Virtual Report Evaluation when using ADVISOR.
- Remote experts submit an Operational Virtual Health Report when using ADVISOR.

DATA SOURCES

OVH utilizes encounter and summary statistics collected from the GTP, ADVISOR call center, OVHRs, and OVHEs to monitor the "health" of the system.

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for CPG compliance. The system review and data analysis are performed by the OVH program.

RESPONSIBILITIES

The OVH program manager and deployed unit is responsible to ensure familiarity, appropriate compliance, and PI monitoring with this CPG.

APPENDIX A: PACE PLANNING FOR TELEMEDICINE

The below tables provide examples and considerations for developing your teleconsultation PACE plan.

Table 1. The patient care and teleconsultation plan will depend on mission analysis.

	Patient Care Plan
Primary: Normal operations	Patient care and evacuation according to doctrine, roles of care, evacuation. If uncertain about the need for evacuation of a routine casualty, and unable to determine this using local resources (e.g. battalion surgeon, regional support medic, etc.), engage the TC routine or urgent system. If a casualty evacuation is delayed beyond planning purposes outstrips LC KSAs +/- local supplies or resources. ENGAGE TC urgent or emergent system through communications plan.
Alternate: Failed communication to one planned expert	If unable to contact the preferred TC solutions, use alternate solution. ▪ If unable to contact the GTP for a routine TC case, call the ADVISOR line. ▪ If unable to contact the ADVISOR line for an urgent/emergent TC case, send message through the GTP.
Contingency: Unable to use established TC solutions	Use ad hoc telemedicine relationships (i.e. "phone-a-friend") to support care-in-place or during evacuation. This could take the form of a phone call, radio transmission, or email. Identify these individuals and contact method beforehand. Consider use of internet-based information to help manage casualty.
Emergency: No network or communications so no TC available	Use un-approved, non-standard local solutions (i.e. local economy, high-risk care by untrained individual) to achieve "best-possible" outcome. Identify hospitals and medical assets in the local area of operation and their contact information. Consider establishing relationships early. Identify manuals, textbooks, how-to-guides for when/if there is no internet and no communications.

Table 2. Telecommunications Technology Plan will depend on mission analysis.

	Technology Plan
Primary	**To Local Support:** Radio per SOP. **To DoD OVH systems:** ▪ **Power**: Electrical grid ▪ **Network**: Fiber or Cable internet ▪ **Equipment**: Dedicated telemedicine equipment (i.e. VTC exam station, room camera, augmented reality device, peripheral devices)
Alternate	**To Local Support:** Operational Chat **To DoD OVH systems:** ▪ **Power**: Solar Cell Battery ▪ **Network**: 4G/LTE Cellular Network ▪ **Equipment**: Mobile Phone/Tablet +/- peripheral exam equipment
Contingency	**To DoD OVH systems:** ▪ **Power**: Gasoline generator ▪ **Network**: Satellite ▪ **Equipment**: Laptop/desktop computer, digital camera, e-mail
Emergency	**To DoD OVH systems:** ▪ **Power**: Batteries ▪ **Network**: Telephone, radio ▪ **Equipment**: Phone, radio

APPENDIX B: VIRTUAL CRITICAL CARE CONSULTATION (VC3) GUIDE

VIRTUAL CRITICAL CARE CONSULTATION (VC3) GUIDE – 2 2017 (v3.1)
To be used with Prolonged Field Care Card

1. Before calling, email image of the casualty (wounds, environment, etc.), "capabilities" (back of page), & vital signs trends:

Critical Care - Dod.criticalcare@health.mil or Dod.vc3@health.mil General/Trauma Surgery - Usarmy.dod.advisor.surgery@health.mil
Orthopedic Surgery - Usarmy.dod.advisor.ortho@health.mil Toxicology - Usarmy.dod.advisor.tox@health.mil
Infectious Disease - Usarmy.dod.advisor.id@health.mil Hematology/Oncology - Usarmy.dod.advisor.hemonc
OB/GYN - Usarmy.dod.advisor.obgyn@health.mil Vet-Europe - Usarmy.dod.advisor.veteurope@health
Vet-Pacific - Usarmy.dod.advisor.vetpacific@health.m

2. If call not answered: a) call next number on PACE or call back in 5 – 10 min.
3. If unable to provide information due to operational security, state so.

This is _____ I am a (job/ position) _____
My best contact info is: _____
YOUR best contact info is (Consultant's number): _____Alternate e-mail: _____

*** PAUSE POINT *** ***CONFIRM CONTACT INFO***

I have ____ (number) of casualties to discuss with you.
The ___ (1st, 2nd, 3rd,…) is a __ year–old ____(gender) _____ (active duty/foreign national/OGA,etc.), who has the following:

Mechanism of Injury or known diagnosis(es) that occurred in (location)
The injury/start of care occurred *hours ago*. Anticipated *evacuation time* is (range)
Injuries/Problems/**S**ymptoms:

Treatments:

He/she is currently (circle) stable/ unstable, getting better/ getting worse/ getting worse rapidly
Known Medication Allergies/Past medical/Surgical history is:

I need help with (*be specific if possible, i.e. "I need help reading this ECG," or "I need help stabilizing this etc.)*

Other Consultants have recommended:

*** PAUSE POINT *** ***Remote Consultant to ask clarification questions*** ***

VITALS (*current* & *trend* as of): HR BP RR SpO2 $EtCO_2$ Temp
UOP(ml/hr) over (# hours) Mental Status (GCS/ AVPU)
EXAM: Neuro Ext/ MSK
Heart Pulses
Lungs Skin/ Wounds
Abd
LABS: ABG: Lactate: Other:

*** PAUSE POINT *** ***Remote Consultant to ask clarification questions*** ***

Don't skip Pause points! Use them to ensure that key information is communicated.

DO NOT Write PII (personally identifiable information) on the call script if you intend to send a digital copy (completed/photograph) via e-mail. Just be prepared to give this information during the call.

Hours since injury/start and anticipated EVAC time:

IMPORTANT
DO NOT USE your time of injury. Consultants are often in different time zones. State the *hours since the injury* occurred or the amount of time you have been caring for the casualty. Give estimate of anticipated time until evacuation.

Patient history: BRIEFLY tell the patient's story using a modified MIST format:
Mechanism of Injury/Illness
Known **I**njuries/Problems
Current **S**ymptoms
Treatments Rendered.
Describe mechanism of injury or history of present illness (when symptoms started, what were they, how they progressed, etc.). List the known problems *explicitly*. Provide assessment of patient stability or clinical trend. Provide any known past medical history/surgical history/allergies.

If you have called other consultants, describe what they have recommended thus far.

Describe what you need the consultant to help you with. Be as specific as possible.

Use these sections to organize notes/ thoughts from the consultant back to you.

Plans/Recommendations

PRIORITY	SYSTEM/PROBLEM	RECOMMENDATION
	Neuro or problem #1	
	CV or problem #2	
	Pulm or problem #3

APPENDIX C: TECHNOLOGY REQUIREMENTS TO GET STARTED

Bring this to your J6, S6 to share what you need….

Using technology in a deployed environment may be a challenge to conduct in an area of operations (AO). Electricity and internet connection, while taken for granted in day-to-day life, are often limited resources in the AO and must be considered in the planning process for telemedical support. Technology should not limit teleconsultation but should augment it.

Ultimately, the type of technology you use should match the clinical question at hand and will be limited by the power, network, and equipment available.

- Use photographs and asynchronous technologies (e.g., e-mail, text) for routine problems or simple updates to a remote expert for their situational awareness. Slow internet connections will delay transmission of images especially ones of sufficient quality to be used. Dermatologic problems, for example, are well suited for using asynchronous technology to make diagnoses and care plans.
- Use synchronous technologies (i.e. phone) to discuss problems like diagnostic dilemmas, care plans with complex risk-benefit tradeoffs, problem solving for management of scarce resources, or timing of patient transport.
- Use video-teleconsultation for procedural telementoring or virtual direct patient care.
- Remote monitoring technology (i.e.telemetry) allows remote experts to help local caregivers identify trends in patient physiology. Using this technology, tele-critical care teams can help local caregivers by monitoring multiple casualties and facilitate better situational awareness. These services may also be utilized to help diminish task saturation (i.e., reduce documentation burden) and enable work-rest cycles.

Minimum: Voice telephone connection with/without asynchronous media to call **ADVISOR** hotline (**1-833-238-7756 DSN: 314-429-9089)** and read from the TCCC card or other form of documentation.

Better: Voice connection WITH concurrent email or photo exchange (i.e., send a photo of the call script, vital signs flowchart, the casualty/care environment, and available kit) closely followed by a phone call. Use a telemedicine report such as the Prolonged Casualty Care (PCC) flowsheet (Appendix B).

Best: Synchronous, real-time audio/video feeds with/without remote diagnostic equipment using the teleconsultation as a guide. If required use the Virtual Critical Care Consultation guide **(**Appendix B) and send a picture of casualty, capabilities, and vital sign trends to the consultant via email or text using operational security and protections of patient privacy.

SOFTWARE

At a minimum, if possible, the local caregiver (LC) and if required, the patient will need access to a secure platform to send messages (picture), make a call or conduct a VTC. There will be times that access to a secure platform is not possible. However, do not delay teleconsultation unless operational situations dictate otherwise (extremely rare). The LC should carefully balance the risk and benefits of waiting for a more secure platform.

HARDWARE

Many HCP/LCs can access TM through secured mobile devices.

- A computer (MC4/NIPR or any CPU) or mobile device
- An integrated or external microphone
- An integrated or external camera

INTERNET

Having a solid internet connection is a crucial piece of successfully accessing telemedicine, especially for telehealth visits conducted by the LC and the patient that require high definition (HD) pictures or a VTC. For Role I/II Access to **NIPR with at least 512kb upload and download speed (1MB preferred),** or **ISP Wi-Fi connection w/same**. Ideally, internet speeds should be at least **15Mbps download and 5Mbps upload**. While video streaming can happen with slower connections and lower definitions (LD), these are the recommended speeds needed to have a clear video experience for the majority of platforms.

APPENDIX D: TAKING GOOD PICTURES

1. Use a well-lit area.
2. Avoid flash photography, if possible.
3. A solid, uniform background is preferred.
4. Have someone else besides the patient take the photograph.
5. If using a cellular phone, use the main (rear-facing) lens, not the "selfie" lens.
6. Make sure the area of involvement is well focused; don't get too close if this makes the image out of focus.
7. For individual lesions, make sure the whole lesion is in the picture.
8. Use a ruler in the image (or, if a ruler is not available, a common object such as a coin) to demonstrate the size of the lesion.
9. For rashes, get a distance view that shows the pattern of the rash and a close-up view that shows the character of the rash.
10. More in-depth training for medical photography on JKO: DHA-US472 Virtual Medical Digital Photography

APPENDIX E: COMMON TELECONSULTATION DEFINITIONS

Asynchronous Communication - unidirectional information flow (i.e., text, e-mail), sometimes known as store and forward, refers to telemedicine that is delivered at a later time from when the patient or another healthcare provider requests it. This could be text-based interactions, a specialist reviewing labs or records at a later time, or a patient conducting an online assessment for medications.

Bandwidth - the amount of information that may move through a network at any point in time. Think of it like a door or a turnstile: only one or two people can fit through at a time. Similarly, packets of digital information flow through wires and those wires, or their connections, are limited in size and thus only allow a certain amount of information to pass through them at a time. Thus, packets must "get-in-line" such that some arrive to their destination before others. If the network is not "point-to-point" and serves multiple users, then these users must share the bandwidth. Some information on the network can be considered "higher priority" than other information. Quality of services protocols allow certain types of information or information from a particular source/user to move more freely (i.e. may go to the "head of the line") than other information.

Consultant/Expert- the clinician who receives the consult from the local caregiver. This may be a designated consultant in a formal system, or a validated and/or trusted expert provider chosen by the local caregiver

Distant Site- a distant site is the location the telemedicine provider is in at the time of remote patient service. Sometimes this is referred to as the consulting site.

Extended consultation- emergent consultation is for patients with critical illness or injury. This concept reflects clinical engagement more than communication modality. This refers to a consultant/expert who remains engaged with the care of a local patient or local patients over time by monitoring physiologic vital signs, audio channel(s), video feed(s), or combinations of these technologies.

Latency - the amount of time it takes information to travel from origination to destination. Most of the time, digital information travels quickly, even across hundreds of miles of distance. Still, using satellite communication to move from one side of the globe to the other, or from the moon to the earth, delays receipt of information. Information may also be slowed if it must pass through filters, firewalls, or scanning software.

Local Caregiver- the person (not necessarily someone with medical training) who is taking care of a patient and who initiates teleconsultation.

Originating Site- the originating site is the location the telemedicine patient is in at the time of remote patient service.

Remote Patient Monitoring- remote patient monitoring refers to technology and programs that help track patient health data at a distant site outside of the hospital or clinic and send that data to care providers in real time. This technology could be in the form of connected healthcare devices like a smartwatch or heart monitor, health monitoring and wellness apps, or connected home devices. Remote monitoring patient data can include vital signs, weight, blood pressure, blood sugar, and other inputs like behavioral health data or symptoms.

Routine consultations are those that do not require immediate assistance. Routine consultations may take many hours to receive a response from a specialist (4-24 hours; median response time is approximately 4 hours).

Synchronous Communication- bidirectional information flow (i.e. voice, video, both). Synchronous telemedicine refers to telemedicine that is performed in real-time via video or phone consult. In practice, this looks like an urgent care provider assessing symptoms of a sore throat and fever, a psychiatrist managing a patient's medication, or a primary care provider conducting a follow-up visit with a patient.

Telemedicine- remote evaluation, diagnosis, treatment, and/or consultation using telecommunications technologies. Telemedicine is a subset of telehealth referring to the specific delivery of clinical healthcare services through telecommunications platforms. Examples of telemedicine could be video consults, phone consults, or patient-provider communication through text messages or a patient portal.

Teleconsultation – or "eConsult" is a caregiver to remote expert discussion about a patient's diagnosis, diagnostic plan, treatment, or management plan using telecommunications technology such as a call, text, video consult, etc.

Urgent non-critical care specialty consultations are those in with remote consultants need to speak with a specialist in order to best manage a patient within hours. This could be a patient related need (i.e. the patient may worsen in the next several hours) or mission specific need (i.e. there is a short communications window or there is a mission essential decision to make like "does this casualty need to get on the evacuation platform that is leaving in the next hour or can he/she continue mission until the next available evacuation time").

VTC – video teleconferencing is the ability to share audio and video signal between two locations to conduct real-time communication. This includes point-to-point (one location communicates to only one other location at a time) and multi-point (multiple locations communication with multiple other locations simultaneously).

APPENDIX F: INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

CRITICAL CARE AIR TRANSPORT CLINICAL PRACTICE GUIDELINE

TRANSCUTANEOUS & TEMPORARY TRANSVENOUS PACING (CPG ID:50)

The goal of this clinical practice guideline (CPG) is to optimize care of patients with hemodynamically significant bradycardia in the aeromedical environment. The series is developed by the Center for Sustainment of Trauma and Readiness Skills and derived from the Tactical Critical Care Evacuation Course.

Major updates

1. A discussion of transcutaneous pacing and indications for the prophylactic placement of a transvenous pacemaker has been included.
2. An overview of physiology of transcutaneous and transvenous pacemakers has been added.
3. Algorithms for loss of capture for transcutaneous and transvenous pacemakers have been developed.
4. An appendix detailing how to program the Medtronic 5388 transvenous pacer has been developed to review the most commonly used dials to make appropriate setting adjustments.

Goal

The goal of this guideline is to provide a review of the physiology, indications, and algorithms for troubleshooting transcutaneous and transvenous cardiac pacing systems. A pre-flight checklist has been developed for patients that are to be evacuated. The algorithms to troubleshoot pacemaker malfunction also include the special conditions encountered by en route care personnel. Appendix A includes a basic transvenous pacemaker programming instruction set. However, it is not intended to replace the device manual.

Background

Myocardial infarction (MI) occurs relatively frequently in the deployed setting, therefore, En Route Critical Care (ERCC) personnel must be familiar with the treatment of its complications. Unstable bradycardia is one such complication, making temporary cardiac pacing a required skill for all deploying providers. Team members need be familiar with the indications for intravenous and transcutaneous cardiac pacing. They must also be to troubleshoot pacemakers in the austere locations within which they operate. For example, electromagnetic radiation from aircraft electronics and RADAR can interfere with transvenous pacemakers and place patients at risk during transport; ERCC personnel must also understand the transvenous pacemaker modes that mitigate the effects of aircraft electromagnetic interference (EMI).[1]

The pacemaker technologies available downrange include temporary transcutaneous and temporary transvenous pacing systems. Portable transcutaneous pacemakers are found at Role1, 2, and 3 facilities, as well as on various Aeromedical Evacuation (AE) platforms. Some Role 3 facilities have the additional capability of placing a temporary transvenous pacemaker before patient evacuation. En route care personnel must be familiar with both types of temporary pacing technologies: transcutaneous and transvenous.

Temporary cardiac pacemakers are only bridges to definitive care. Patients with hemodynamic unstable bradycardia often require cardiac catheterization, advanced cardiac electrophysiologic studies, and potentially permanent pacemaker placement. None of these medical capabilities are available downrange. Therefore, patients who require temporary pacing should be categorized as “urgent” for evacuation purposes, as mortality and morbidity are increased if definitive care is delayed.[2]

If the ERCC provider is not experienced with managing or troubleshooting a transvenous pacemaker, the theatre cardiologist may be brought on the flight as mission-essential-personnel (MEP) to augment the ERCC team. If a theater cardiologist is not available, the global cardiologist consult service

(cards.consult.army@mail.mil) can be utilized to help formulate the best care plan given that equipment and resources available.

The physiology, indications, and complications associated with temporary cardiac pacing will be discussed below. There will also be a focus on special considerations associated with AE.

Physiology of Noninvasive Transcutaneous Pacing

Both the right and left ventricles are stimulated with transcutaneous pacing. The atria are frequently stimulated in a retrograde fashion; this produces atrioventricular dyssynchrony which decreases cardiac output by about 20% from the loss of an atrial kick. Although a patient with symptomatic bradycardia will experience an increase in cardiac output and mean arterial pressure because of pacing, the cardiac output will not usually return to pre-bradycardia levels. This 20% cardiac output decrease, however, will usually be well tolerated unless left ventricular function is severely diminished.[3]

Studies have demonstrated that transcutaneous pacing does not injure the myocardium and from this perspective there is no time limit associated with transcutaneous pacing. Capture rates with the Zoll MD monitor (used by ERCC) are high and vary according to the device and patient population; some published capture rates are up to 96%, although this may be best case scenario.[4] Limitations of transcutaneous pacing include skin damage and patient discomfort.

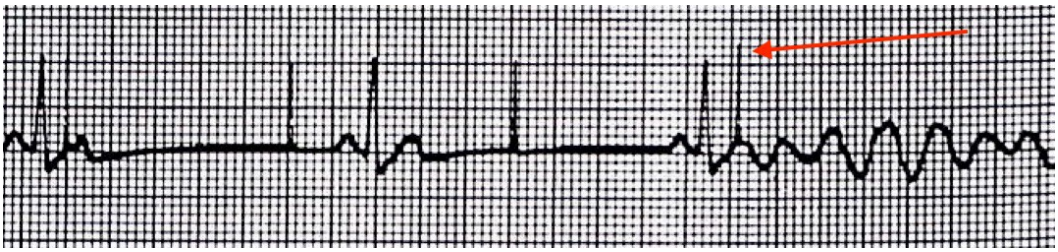
Physiology of Transvenous Pacing

Transvenous pacemakers can do two things: (1) pace the heart and (2) sense the intrinsic cardiac rhythm. Unlike transcutaneous pacing, a transvenous pacemaker can pace the atrium, ventricle, or both; the term dual chamber pacemaker is used when both the atrium and ventricle can be stimulated. Depending on the clinical circumstance and the pacemaker settings, a dual chamber pacemaker can maintain atrioventricular synchrony and therefore cardiac output.[5]

The transvenous pacemaker can pace the heart at a fixed rate regardless of the underlying heart rhythm; this is termed asynchronous. It can also sense the heart's electrical activity to determine if it is necessary to stimulate a cardiac contraction to maintain a predetermined heart rate; this is termed synchronous. Therefore, in the synchronous mode the pacemaker does not fire if the intrinsic heart rate is above a predetermined value. In the asynchronous mode, the pacer fires at a fixed rate regardless of the underlying rhythm.

The entire point of pacemaker sensing is to avoid the R-on-T phenomenon (he superimposition of an ectopic beat on the T wave of a preceding beat) that can degenerate into ventricular tachycardia/ventricular fibrillation (VT)/(VF) (see red arrow in Figure 1 below). This is because a "sensing" pacemaker will not produce an electrical impulse that is "too close" to an intrinsic cardiac contraction. Therefore, any environment that interferes with a pacemaker's ability to sense properly will place the patient at risk for VT/VF. Two clinical settings found downrange that can disrupt pacemaker sensing are (1) the operating room and (2) the AE environment; in both situations EMI is the culprit.

Figure 1. An example of R-on-T from a pacemaker



The asynchronous mode protects the patient from R-on-T when the pacemaker is not sensing correctly, the pacemaker rate is set ***higher*** than the patient's intrinsic heart rate. In this mode, the provider becomes the sensor.

To avoid VT/VF, it is imperative that the pacemaker rate be set to a value greater than the patient's intrinsic heart rate; this also applies to transcutaneous pacing.

Important Contraindications Specific to Transvenous Pacemakers:[1]

- Asynchronous pacing is contraindicated in the presence of intrinsic cardiac rhythms, unless there is EMI that renders the pacemaker's ability to sense the heart's intrinsic electrical activity ineffective.
- Atrial pacing is ineffective in the presence of atrial fibrillation or flutter.
- Single chamber atrial pacing is contraindicated in the presence of AV conduction disorders.
- Pacing modes that allow sensing in the atrium to trigger a ventricular response are contraindicated in the presence of rapid atrial arrhythmias such as atrial fibrillation or atrial flutter.

Complications of Temporary Transvenous Pacing

Conventional temporary transvenous pacing is associated with substantial complications, including local infection, thrombosis, and a lead dislodgement rate ranging from 10 to 37%.[5]

Lead dislodgment highlights the importance of having a transcutaneous pacing system in place at all times, particularly in-flight where patient transfers and movement may increase the dislodgement rate.

Temporary Pacing & Prophylactic Transvenous Pacemaker Placement

Indications for Temporary Cardiac Pacing[6]

Indications for pacing a patient with bradycardia are hemodynamic instability (hypotension), acute altered mental status, ongoing severe ischemic chest pain, congestive heart failure, syncope, 3rd degree heart block, bradycardia unresponsive to drug therapy, or other signs of shock.

Boluses or infusions of chronotropic medications, such as atropine, epinephrine, dopamine, or isoproterenol may be considered before initiating pacing. Note that atropine, however, is typically not effective for Mobitz type II and complete heart blocks. Do not delay initiating pacing with signs of shock if bolus medications are not immediately available.

Sinus bradycardia is common shortly after ST elevation MI (STEMI), particularly after inferior wall infarcts; if symptomatic, atropine may be used followed by temporary transcutaneous pacing if necessary.

Indications for Prophylactic Transvenous Pacemaker Placement[6]

The incidence of complete heart block is nearly 4% with inferior/posterior MI. In certain cases, a transvenous pacer may need to be placed before flight after discussion with the theatre cardiologist.

Prophylactic placement of a temporary transvenous pacing system is recommended for high-grade AV block and/or new bundle-branch (particularly with LBBBs) or bifascicular block in patients with anterior/lateral MI.

High-grade AV block with inferior/posterior STEMI usually is transient and associated with a narrow complex/junctional escape rhythm that can be managed conservatively. Application of transcutaneous pacing pads for potential use is reasonable in the hospital setting; a discussion with cardiology as to whether a transvenous pacing system should be placed prophylactically before evacuation should occur.

Bradyarrhythmias are common with right heart MI's. An adequate heart rate is essential to maintain cardiac output with right ventricular dysfunction. Transvenous pacer placement before flight should be considered if bradyarrhythmias are present. However, it may prove problematic with an ischemic right ventricle: be prepared to pace transcutaneously.

Another indication for transvenous pacing is if the patient is too diaphoretic to allow good electrode-to-skin adhesion for transcutaneous pacing. Large pectoral muscles also increase capture thresholds; therefore fit muscular patients may be better served with a prophylactic transvenous pacemaker in certain cases. Cardiology should be included in the decision when planning these for contingencies.

As a general rule, transcutaneous pacing should not be maintained for longer than 24 hours without converting to a transvenous pacemaker.

Pacing Equipment Available to ERCC

ERCC personnel must be familiar with the operation of the Zoll MD Monitor. Transcutaneous pacing is performed with the monitor and dermal electrodes during patient movement by ERCC.

The portable transvenous pacemaker generator currently stocked downrange is the Medtronic 5388 dual chamber pacemaker unit. ERCC members should also become familiar with this unit prior to transporting a patient. Appendix A will highlight some important programming aspects of the Medtronic 5388, to include safe modes to mitigate EMI's negative effects. The appendix is not meant to replace the device's user manual. All ERCC personnel should review the manual before deploying; the link to an electronic copy on the Medtronic website is:
http://manuals.medtronic.com/wcm/groups/mdtcom_sg/@emanuals/@era/@crdm/documents/docume nts/198092001_cont_20071214.pdf

Pre-flight Checklist & Considerations for ERCC Movement

1. A chest x-ray should be done to verify correct transvenous pacer placement and to exclude pneumothorax from pacer placement.

2. A 12-lead ECG and pulse exam should be performed to confirm consistent mechanical capture.

3. Consider pre-flight intubation if transporting a patient requiring transcutaneous pacing. Transcutaneous pacing is painful and will require analgesia and sedation; this is more easily accomplished in the intubated patient. Note that the force of the skeletal muscle contraction, rather than the pacemaker's output in mA, predicts patient discomfort. Discomfort appears to be inversely related to age, possibly due to the older patient having less muscle mass. Therefore, young muscular males may be the most susceptible to transcutaneous pacer intolerance.

4. ERCC personnel should not perform transvenous dressing changes in-flight. If appropriate, have the Role III nurse change the dressing prior to departure.

5. Secure the TVP unit directly to the patient, ensuring it does not fall during patient movement, which could potentially cause lead displacement and loss of capture.

6. A central line and arterial line should be placed prior to flight. If the symptomatic bradycardia is secondary to an acute MI, ensure central and arterial lines are placed at compressible locations if full anticoagulation and/or fibrinolytics may be used.

7. Correct all electrolytes pre-flight to include potassium, magnesium, calcium and phosphorous. Potassium and phosphate replacements are not in the ERCC allowance standard and must be obtained from the Role III prior to departure.

8. Review all cardiac studies to include ECGs, echocardiogram results, and troponin levels.

9. Plan for pacing system malfunction by obtaining (or preparing) infusions of chronotropic medications: epinephrine, dopamine, or isoproterenol. Isoproterenol must be obtained from the Role III as it is not included in the ERCC allowance standard.

10. A request for the Role 3 cardiologist to accompany the AE as mission-essential-personnel (MEP) is possible if the ERCC physician has limited experience with transvenous pacing.

11. After the patient has been transferred to the aircraft, reassess all leads and connections to ensure electrical capture and check a pulse to verify that mechanical capture has not been lost during patient movement on the ground.

12. Patients being paced require continuous and close observation because pacing thresholds can increase over time; patients should be monitored to ensure continuous mechanical capture during flight.

13. An extra battery for the transvenous pacing unit should be taped to the back of the unit or kept immediately available. Confirm that the battery is fully charged prior to departure.

Plan for Loss of Capture with Transcutaneous Pacing In-flight

- Good skin-to-electrode contact lowers transthoracic impedance and improves electrical capture of the heart. All chest hair under the electrode should be clipped or removed.
- Replace pacer pads every 24 hours, regardless of if they are being used. The accumulation of sweat under the pads can result in loss of capture if pacing is initiated.
- Moving the posterior electrode to the right of the spine increases the capture threshold by 15%, as compared to placement over the spine. Therefore, to maximize capture the posterior pad should be under the right scapula.
- Higher capture thresholds for transcutaneous pacing have been found in patients with the following factors: hypoxia, acidosis, pulmonary emphysema, pericardial effusion, large pectoral muscles, and certain medications (e.g., antiarrhythmics, beta blockers, calcium channel blockers).

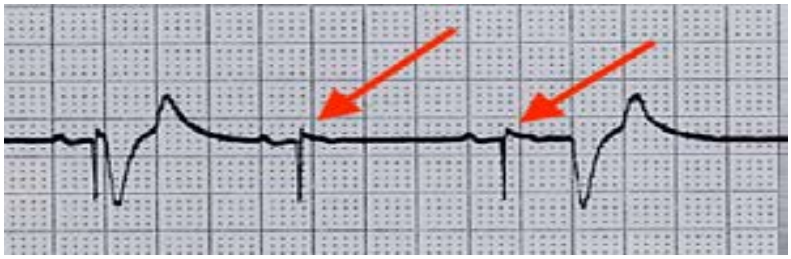
Steps to take for failure to capture in-flight are:

1. Increase the mA until electrical and mechanical capture are confirmed.
2. Make sure the pacing electrodes are well adhered to the skin.
3. Check for correct placement of the electrodes (posterior electrode under the right scapula). You may find the posterior electrode in the litter when the patient is diaphoretic or restless.
4. Move the pacing (negative) electrode to another place on left precordium.
5. Treat any acidemia and/or hypoxemia present.
6. Consider an infusion of a chronotropic agent if the above steps fail to achieve capture; also consider flight diversion. An in-flight cardiology consult would be appropriate.
7. ***Intermittent loss of capture must be addressed urgently, as sudden and complete loss of capture will likely result in asystole.***

Plan for Loss of Capture with Transvenous Pacing In-flight

An example of loss of capture with ventricular pacing is shown in Figure 2. ***Note****: only the first QRS complex is associated with a pacing spike, the red arrows mark "pacing spikes" that do not capture.*

Figure 2. Ventricular loss of capture



All patients requiring temporary transvenous pacing should be transported with transcutaneous pads in place and connected to a monitor that has external pacing capability. The monitor should be preprogrammed so immediate transcutaneous pacing can be initiated. If the temporary pacemaker is discontinued abruptly, asystole may result.

Steps to take for failure to capture in-flight are:

1. Check the battery and replace as needed. Transcutaneous pacing may be required until completed. The battery should be checked twice daily.

2. Increase the mA, then decrease the sensitivity to zero.

3. If the catheter has a balloon, it should be inflated (with saline) and the catheter advanced to regain capture; once capture is obtained the balloon should be deflated. Sometimes, however, the catheter requires withdrawal (with the balloon down) to regain capture. For these maneuvers, the pacer catheter should have been placed through a sterile sleeve so that in-flight adjustments can be easily done. The provider must understand the risks associated with catheter advancement and withdrawal (i.e. cardiac perforation). The back-up plan to catheter adjustment is transcutaneous pacing, which may be the safest option depending on the clinical scenario and experience of the provider.

4. Consider an infusion of a chronotropic agent if the above steps fail to achieve capture; also consider flight diversion. An in-flight cardiology consult would be appropriate.

5. Treat any acidemia and/or hypoxemia present.

Intermittent loss of capture must be addressed urgently, as sudden and complete loss of capture will likely result in asystole.

Placement of Transvenous Pacing System

- Placement of a temporary transvenous pacemaker requires central venous access with a 6.0 French (Fr) percutaneous introducer catheter. If an 8.5Fr introducer is used (typically used in trauma resuscitations), it may leak blood from around the pacing catheter.
- Catheter placement in the right internal jugular vein is preferred. Placement in the left subclavian is also acceptable, but this location should be avoided in patients who are being anticoagulated or who may need fibrinolytics. Fluoroscopic guidance is not absolutely necessary at these pacer insertion locations, but a chest x-ray should be obtained to rule out hemothorax, pneumothorax, and to confirm appropriate position of the pacer wire.
- Standardization of pacemaker catheters across military treatment facilities has not been achieved; review the manufacturer's instructions set prior to using.
- If the pacer catheter has a balloon, it should be inflated (with saline) while the catheter is advanced and capture is obtained. Once capture is obtained, the balloon should be deflated and left deflated. The pacemaker catheter should be placed through a sterile sleeve so that in-flight adjustments can be done easily.

Transvenous Pacemaker Modes

The different modes for transvenous pacing are defined with a three-letter code:

1. First letter defines the area of the heart paced: atrium (A), ventricle (V), or both atrium and ventricle (D).

2. Second letter defines the area of the heart sensed: atrium (A), ventricle (V), or both atrium and ventricle (D).

3. Third letter defines what the pacemaker does with the sensing information. Sensing can result in:

    - Pacemaker being inhibited from firing (letter I used to denote "inhibited").
    - No effect on how the pacemaker fires (letter O used to refer to "none").
    - Both the atria and ventricle are paced (letter D used to refer to atrium and ventricle, or A+V).
    - Only the atrium is paced (letter A used to refer to atrium).
    - Only the ventricle is paced (letter V used to refer to ventricle).

The most commonly used pacing mode for the treatment of bradyarrhythmias is ventricular demand pacing. When it is important to maintain cardiac synchrony (treating a critically ill patient with impaired ventricular function) a dual chamber pacemaker is preferred as it can improve cardiac output by up to 20%. Ventricular demand pacing, however, will be satisfactory for most patients.

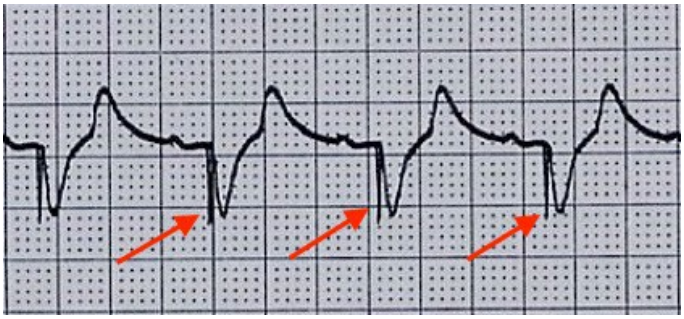
Ventricular demand pacing is the mode of choice during patient evacuations *because attaining the correct electrode position when "floating" the transvenous pacemaker is relatively simple. It will be well tolerated provided that the left ventricular function is not severely depressed. It is also the least sensitive to small changes in catheter positions.*

Settings for temporary ventricular pacing are VVI and VOO.

- In mode VVI (synchronous mode), the ventricle is paced, as well as sensed. If the pacemaker's pulse generator senses an impulse created by the heart, the pacemaker's impulse is not sent, thus the pulse generator is inhibited. This mode is used to prevent R-on-T complications when there is an underlying ventricular rhythm. This is the preferred mode, unless EMI is present.
- In mode VOO (asynchronous mode), the ventricle is paced at a fixed rate and there is no sensing; electrical impulses are delivered regardless of the underlying ventricular rhythm. This mode is best used if electrocautery is being used (during surgery), and during periods of excessive electrical stimulation from EMI due to aircraft electronics. The rate with VOO must be greater than the patient's intrinsic heart rate to avoid R-on-T which can result in VT/VF.

An example of ventricular pacing is shown in Figure 4. Notice the wide QRS complexes; they are normal with ventricular pacing and each "pacing spike" (marked by red arrows) is associated with such a complex.

Figure 4. Ventricular pacing with capture



Transvenous pacemaker modes to use for particular conduction pathologies are summarized in Table 1.

Table 1. Transvenous Pacemaker

Code	Definition	Indication
AOO	Atrial paced, no sensing, no inhibition	Sick sinus syndrome with intact conduction system, use for in-flight EMI
AAI	Atrial paced, atrial sensed, inhibited by atrium	Sick sinus syndrome with intact conduction system
VOO	Ventricular paced, no sensing, no inhibition	Third degree heart block with atrial fibrillation, use for in- flight EMI
VVI	Ventricle paced, ventricle sensed, inhibited by ventricle	Third degree heart block with atrial fibrillation
DOO	Dual paced, no sensing, no inhibition	Third degree heart block without atrial fibrillation, use for in-flight EMI
DVI	Dual paced, ventricle sensed, inhibited by ventricle	Third degree heart block with supraventricular tachycardia
DDD	Dual pace, dual sensed, dual inhibited	Third degree heart block

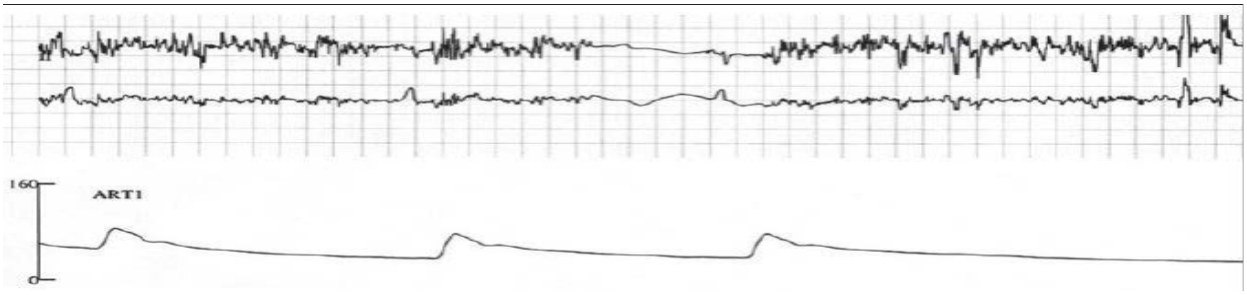
Transvenous Pacing Scenarios with Associated ECG Tracings

(1) Electromagnetic Interference

- If electromagnetic interference is present and inhibiting the pacemaker from firing, then the pacemaker should be switched to an asynchronous mode such as dual- chamber asynchronous pacing DOO or VOO.
- Use DOO for third degree heart block without atrial fibrillation.
- Use VOO for third degree heart block with atrial fibrillation.
- Remember that the rate with VOO and DOO must be greater than the patient's intrinsic heart to avoid R-on-T which can result in VT/VF.

A typical ECG with EMI will look similar to the tracing in Figure 5 below.

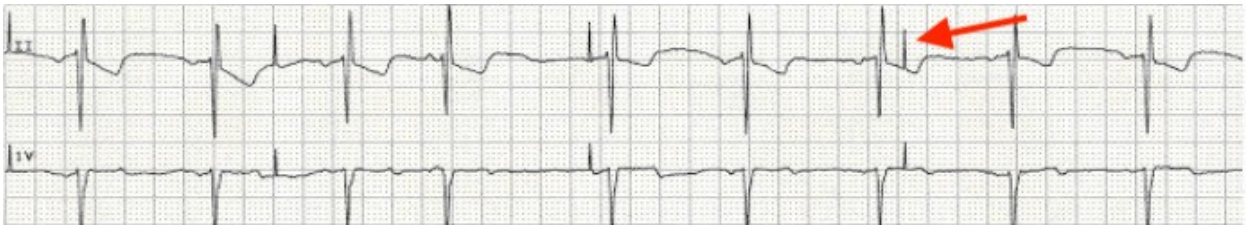
Figure 5. An example of EMI that causes pacemaker inhibition



(2) Failure to sense

Failure to sense (or undersensing) is shown in the Fig. 6. It occurs when the pacemaker fails to recognize spontaneous myocardial depolarization. This is identified by the generation of an unnecessary pacing spike (one that follows too closely behind the patient's QRS complexes). To correct this, consider increasing the sensing threshold, see Appendix A.

Figure 6. An example of failure to sense (or undersensing)



(3) Loss of capture

An example of loss of atrial capture is shown in Figure 7 below.
Note there are no p waves that follow the "upward" atrial "pacing spikes."
Refer to Appendix A for how to increase the atrial Ma.

Figure 7. An example of loss of atrial capture

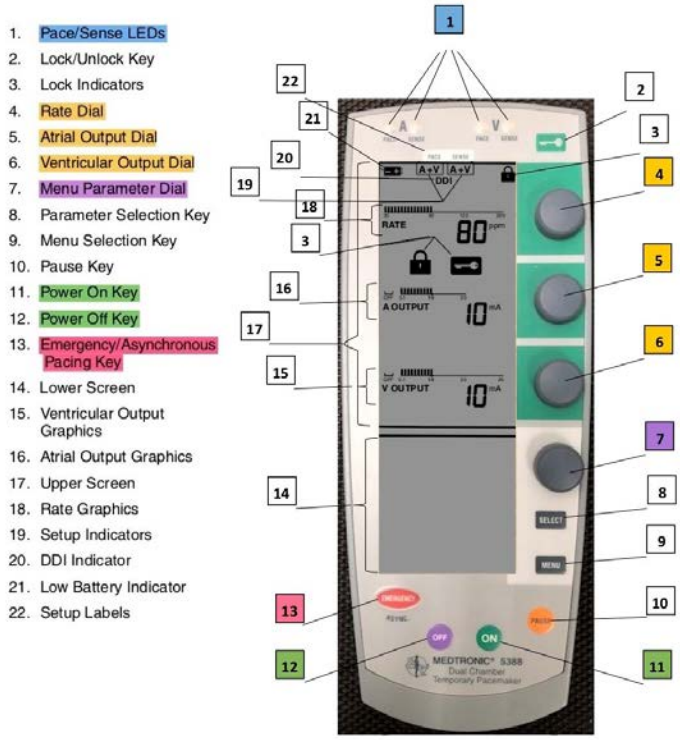
Appendix A: Overview of the Medtronic 5388 Dual Chamber Pacemaker

A schematic of the Medtronic 5388 is shown below (Figure A1); a few selected dials and buttons will be explained within this appendix. The Medtronic manual should be used for a comprehensive review of the device; the manual was used to construct this brief review in the event that the Medtronic manual would be unavailable in the deployed setting.

Figure A1. Schematic of the Medtronic 5388



POWER ON/OFF: The ON button is marked in green (number 11, Figure A1) and the OFF button is number 12 above. Press the ON key once. The upper screen lights up and the pacers initiates a self-test. Once a successful self-test is completed the following occurs: A sufficiently charged battery will allow the device to begin sensing and pacing in both the atrium and ventricle at the following nominal parameter values. Press the "OFF" button twice within 5 seconds. After the first press, a message appears in the lower screen telling the user to press OFF a second time to turn the device off.

Table A1. The power up values for the 5388 dual Medtronic pacemaker

Base Rate	**80 per min**
A output and V output	10 mA and 10 mA
A sensitivity	0.5 mV
V sensitivity	2.0 mV
A Tracking	ON

EMERGENCY/ASYNCHRONOUS BUTTON: Press this key (number 13, Fig A1) once to select high-output, dual- chamber asynchronous (DOO) pacing at any time, whether the device is off or locked. Use caution to avoid accidentally activating the Emergency key. This button should be used if electromagnetic interference causes over sensing inhibiting the pacemaker from firing causing hemodynamic instability. The device will pace at the following values:

Table A2. Emergency Values

Base Rate	**80 per min**
A output and	20 mA
V output	25 mA
A sensitivity	ASYN (no sensing)
V sensitivity	ASYN (no sensing)

Adjusting the rate, A output, and V output in emergency mode: These parameters can be adjusted using the three upper dials (numbers 4, 5, and 6) on the right side of device marked in yellow in Figure A1; these dials will be detailed below. To return the device to demand or synchronous pacing:

- Press the ON key once if the asynchronous pacing message is displayed in the lower screen.
- Press the ON key twice if the asynchronous pacing message is not displayed in the lower screen. The first press of the ON key causes the asynchronous message to appear.
- The number 14 in Figure A1 identifies the lower screen.

The device will begin synchronous pacing with the following values:

Table A3. Current Settings

Base Rate	**Current settings**
A output and	Current settings
V output	Current settings
A sensitivity	0.5 mV (nominal)
V sensitivity	2.0 mV (nominal)

ADJUSTING RATE, A OUTPUT, AND V OUTPUT: the parameter settings are displayed numerically and graphically. The dials for adjustment are the numbers 4, 5, and 6 respectively (marked in yellow, Figure A1). The line next to each dial shows the range available for each parameter. The liner graph appears above the corresponding numerical value.

Rate dial (number 4 in Figure A1): The optimal RATE setting once the device turns on is 80 BPM. The pacing rate ranges from 30 to 200 beats per minute (BPM). Turning the RATE knob clockwise increases the rate, and counter-clockwise decreases the rate.

A (Atrial) OUTPUT dial (number 5 in Figure A1: The atrial output ranges from 0.1 to 20 mA. Turn the dial clockwise to increase A OUTPUT. Turn the dial counterclockwise to decrease or turn A OUTPUT OFF. When A OUTPUT is set to OFF, both the atrial output and the atrial sensitivity are turned off (i.e., there is no atrial pacing or sensing).

V (Ventricle) OUTPUT dial (number 6 in Figure A1): The ventricular output ranges from 0.1 to 25 mA. Turn the dial clockwise to increase V OUTPUT. Turn the dial counterclockwise to decrease or turn V OUTPUT to OFF. When V OUTPUT is set to OFF, both the ventricular output and the ventricular sensitivity are turned off (i.e. there is no ventricular pacing or sensing).

PACE LEDs

- Two green LEDs at the top of the device, marked PACE, number 1 in Figure A1, indicate delivery of a pacing pulse but do not necessarily indicate the pacing pulse has initiated cardiac stimulation.
- The green LED next to the A flashes each time the device delivers a pacing pulse on the atrial channel.
- The green LED next to the V flashes each time the device delivers a pacing pulse on the ventricular channel.

Adjusting Atrial and Ventricular Sensitivities

- The lower screen (number 14, Figure a1) allows adjustment of the atrial and ventricle sensitivities.
- Menu 1 provides access to the:
  - Atrial sensitivity (A SENSITIVITY),
  - Ventricular sensitivity (V SENSITIVITY),
  - A-V Interval (A-V INTERVAL), and
  - Atrial tracking option (A TRACKING).
- Depressing the Menu button (number 9, Figure A1) and then using the Select button (number 8, Figure A1) to choose Menu 1 allows access to change the sensing values for the atrium and ventricle.
- Unless manually adjusted, the atrial sensitivity (A SENSITIVITY) is set to the nominal value of 0.5 mV.
- When selected, the A SENSITIVITY may be adjusted between 0.4 and 10 mV by turning the Menu Parameter dial.
- Unless manually adjusted, ventricular sensitivity (V SENSITIVITY) is set to the nominal value of 2.0 mV.
- When selected, the sensitivity may be adjusted between 0.8 and 20 mV by turning the Menu Parameter dial.

TRANSFUSION FOR THE MILITARY WORKING DOG

Publication Date: 10 Dec 2019, CPG ID:77

Photo credit: US Military Working Dog Teams National Monument, Lackland AFB, TX

These clinical practice guidelines focus on transfusion for military working dogs injured as the result of trauma in a forward deployed environment and will focus only on canine blood products expected to be found in theater.

INTRODUCTION

Military Working Dogs (MWDs) are at the same risk for injury as their human counterparts and when they are severely injured, best practice for resuscitation mirrors those recommended for humans.[1] A recent study of trauma in MWDs shows that explosions, gunshot wounds and lacerations account for the vast majorities of injuries sustained within the Central Command area of responsibility.[2] In severe cases, these mechanisms of injuries could require resuscitation with blood products.[3,4] Hemostatic resuscitation has been shown in a many species to be superior to resuscitation with crystalloids or synthetic colloids[5,6] and should therefore be considered the first-choice resuscitation product in severely wounded MWDs.

Note: only canine blood products should be considered for transfusion to an MWD as transfusion of human blood products into canines carries a high likelihood of an incompatible hemolytic reaction. [7]

INDICATIONS

Transfusion therapy is indicated for MWDs experiencing any condition (trauma, neoplasia, other) that results in acute blood loss or clinical anemia, or that significantly increases their bleeding risk (e.g., severe thrombocytopenia, Acute Traumatic Coagulopathy/Trauma-Induced Coagulopathy,[8] other). Consider transfusion therapy as a first-line intervention for perioperative hemodynamic optimization in MWDs that have suffered major trauma. These guidelines focus on transfusion for MWDs injured as the result of trauma in a forward deployed environment and will focus only on canine blood products expected to be found in theater – specifically canine Whole Blood, Fresh Frozen Plasma and Freeze Dried Plasma. These guidelines should therefore not be used for all conditions.

Table 1. Definitions

Definitions
Acute Blood Loss/Hemorrhage indicated if one or more of the following: • Estimated or anticipated **blood loss > 20%** of estimated total blood volume (eTBV),   • ~ 400 – 500 mL in a 25 kg MWD based on eTBV of 85 mL/kg in MWDs. • Systemic signs of hypoperfusion (See Table 6.) • SBP < 90 mm Hg or drop in SBP by ≥ 30 mm Hg • Shock index (SI) > 1.0 - (Heart rate/systolic blood pressure)[9] • Hypothermia (< 99°F or < 37°C) • Hyperlactatemia (≥ 5 mmoL/L) and / or Base Excess -6.6 or lower

Clinical Anemia resulting in:
• Tachycardia (HR ≥ 160 ± 20 beats/minute) ± bounding femoral pulses
• Pale to white mucous membranes
• Depressed mentation
• Hematocrit <20%, Hemoglobin < 7 g/dL
Note: the above values are not transfusion triggers in dogs. Clinicians are encouraged to use multiple clinical and laboratory values to determine the need for transfusion in an anemic dog.
• Presence of worsening anemia with signs of impaired oxygen delivery:
  • Hypoxemia (SpO2 < 90%, room air)
  • Elevated RR (> 40 breaths/min) with increasing respiratory effort

Definitions

Clinical Coagulopathy
• Clinical signs of spontaneous hemorrhage with one of the following:
  • Viscoelastic tracing (thromboelastography and rotational thromboelastometry [TEG / ROTEM]) demonstrating decreased clot strength of < 40% of mean reference value [(ROTEM - Maximum Clot Firmness (MCL) or TEG - Maximal Amplitude (MA)]
  • Prolonged coagulation assays (activated Partial Thromboplastin Time [aPTT]; Prothrombin Time, [PT]) > 1.5 times the mean laboratory reference interval.

Standard transfusion triggers are generally not applied to canine medicine but rather the clinical condition of the MWD is assessed to determine the appropriateness of a transfusion. The following should be considered in the assessment for blood transfusion needs in a MWD:

Table 2. Mechanism of injury, anatomical site and severity of injury

Mechanism of injury, anatomical site and severity of injury

1. **Mechanism of injury (MOI)**
  a. Blunt* - Vehicular, primary blast injury.
  b. Penetrating*
  • Stabbing, ballistic, impalements, bite wounds, secondary blast injury.
  • Higher-velocity, higher-kinetic-energy vs. low-velocity, lower kinetic
  c. Other: Acceleration/deceleration; shear; and crush.
 	
*Major trauma from blunt or penetrating MOIs present the greatest risk for massive hemorrhage warranting transfusion needs.[3]

2. Anatomical location: Internal versus External
  a. Cavitary bleeding (thoracic, peritoneal, retroperitoneal) is considered a major source of hemorrhage in trauma patients.
  b. Canines suffering blunt trauma to the abdomen have a higher risk for mortality due to unrecognized internal bleeding.[10]

3. Severity of Trauma
  a. Polytrauma
  b. Modified Animal Trauma Triage (ATT) score (see Table 4). [10,11]

Used collectively, the MOI (e.g., blunt force from primary blast wave), anatomical injury patterns (e.g., thoracic versus abdominal), external physical examination findings (e.g., bruising around the umbilicus, distended abdomen with positive fluid wave test, localized pain or tenderness, etc.) and accompanying vital parameters may increase the index of suspicion and direct attention to the most likely sources of occult hemorrhage.

Table 3. Physical parameters and laboratory indicators to evaluate the presence of hemorrhagic circulatory shock warranting hemostatic resuscitation

Physical parameters and laboratory indicators to evaluate the presence of hemorrhagic circulatory shock warranting hemostatic resuscitation
1. Physical: a. Mentation b. Heart rate (HR) and rhythm, Capillary Refill Time (CRT) and mucous membrane color (MM) c. Femoral pulse rate and quality d. Rectal temperature e. Respiratory rate (RR) and respiratory effort
2. External Injury patterns Bruising around the umbilicus, distended abdomen with positive fluid wave test, localized pain or tenderness, other.
3. Laboratory and Diagnostic findings a. Packed cell volume (PCV) and Total solids (TS) b. Lactate and Base Excess (BE),[12] venous or arterial c. Pulse oximetry (SpO2) d. Systolic Blood Pressure (SBP) e. Shock index (SI)
4. Coagulation: a. Coagulation assays (aPTT; PT) b. Viscoelastic tests (e.g. TEG®, ROTEM®, Sonoclot®) c. Platelet counts d. Fibrinogen
5. Diagnostic imaging a. Survey radiographs b. Focused Assessment with Sonography for Trauma (FAST)[13] • Abdominal FAST (AFAST) with abdominal fluid score (AFS) • Thoracic FAST (TFAST) – Pericardial site and Diaphragmatic-hepatic site
6. Other Abdominocentesis or Diagnostic Peritoneal Lavage (DPL) with body cavity fluid analysis.
***Note**: Although many of these modalities are not available at the point-of-injury, they may become available as the MWD casualty is transported to higher roles of medical care.*

Table 4. Modified Animal Trauma Triage (ATT) Score

Modified ATT Score[11]	
Perfusion	
MM pink/moist, CRT 2 sec, T ≥ 100F, strong or bounding femoral pulse quality	0
MM hyperemic **or** pale pink, MM tacky, T ≥ 100F, CRT 0–2 sec, fair femoral pulses	1
MM very pale pink & tacky, CRT 2–3 sec, T < 100F, detectable but poor pulses	2
MM gray/blue/white, CRT > 3 sec, T < 100F, non-palpable femoral pulses	3
Respiratory	
Regular respiratory rate with no stridor, no abdominal component to respiration	0
Mild increased respiratory rate and effusion, ± abdominal comp, mild upper airway sounds	1
Mod increased respiratory rate and effort, some abdominal component, elbow abduct, mod increased upper airway	2
Marked respiratory effort **or** gasping/agonal respiratory, little/no air passage	3
Neurologic	
Central: consciousness: alert to slightly dull, interest in surrounding. Peripheral: normal spinal reflexes; purposeful movement and nociception in all limbs.	0
Central: dull/depressed/withdrawn. Peripheral: abnormal spinal reflexes with purposeful movement and nociception intact in all 4 limbs.	1
Central: unconscious, responds to noxious stimuli. Peripheral: absent purposeful movement with intact nociception in 2 or more limbs **or** nociception absent in 1 limb, decreased anal or tail tone.	2
Central: nonresponsive to all stimuli, refractory seizures. Peripheral: absent nociception in 2 or more limbs, absent tail or perianal nociception.	3
***Score 0–3 (3 = most severe)** for each of the above 3 categories. Increased ATT score equates to more severe injury.	

Table 5: Diagnostic Recommendations

Diagnostic Recommendations
• Obtain serial (not a one-time measure) PCV and total solids to help assess the degree of ongoing hemorrhage. It is important to interpret the PCV in light of the TS concentration, and the acuteness of the blood loss.
• Incorporate serial measurements of base excess and lactate in conjunction with traditional clinical perfusion parameters (e.g., heart rate, pulse quality, mucous membranes, capillary refill time, mentation, body temperature, and arterial blood pressure) as end points of perfusion. • Monitor for changes in vital signs and laboratory parameters that indicate progressing hypoperfusion such as increasing heart or peripheral arterial pulse rate with decreasing peripheral pulse strength, pale MM, prolonging CRT, and worsening anemia and lactate /BE values.
• Utilize FAST to evaluate the abdominal cavity, retroperitoneal space, pleural space, gastrointestinal tract, and fascial planes around fractured bones for areas of "hidden" ongoing hemorrhage that may lead to life-threatening hemorrhagic shock.

• Conduct serial assessments to evaluate whether cavitary effusion is developing or worsening over time.
• Use viscoelastic tests, when available, to identify the presence of a coagulopathy, predict transfusion needs, and evaluate the response to therapy. • When viscoelastic tests are not available, transfuse blood products as needed to maintain PT and aPTT <1.5× of mean reference values.
• Consider ongoing retroperitoneal hemorrhage for any blunt abdominal trauma patient with refractory hemorrhagic shock and declining PCV/TP values, but no significant findings on abdominocentesis, DPL, or AFAST.
FAST - Focused Assessment with Sonography for Trauma; **PT** – Prothrombin Time; **aPTT** – activated Partial Thromboplastin Time; **DPL** – Diagnostic peritoneal lavage;

Table 6: Clinical and diagnostic considerations for predicting transfusion needs

Clinical and Diagnostic Considerations for Predicting Transfusion Needs
General
• MWDs that present with overt hypotension or a high shock index consider early institution of hemostatic resuscitation (transfusion therapy is preferred to crystalloid as the initial resuscitation fluid for management of hemorrhagic shock).
• Common clinical manifestations in canine trauma patients warranting blood transfusions, include[3]: • **Tachycardia** (160 $\pm$ 20 beats/pulses per minute) • **Tachypnea** (> 40 breaths per minute) with increased respiratory effort. • **Hypothermia** (< 99°F or < 37°C) • **Hyperlactatemia** (≥ 5 mmoL/L)
• In face of major blunt or penetrating trauma, a **SI > 1.0** is a sensitive and specific adjunct tool for detecting acute small volume blood loss in dogs. It serves as a more valuable diagnostic assessment for detecting acute occult blood loss, as compared to assessing HR and SBP alone. Consider this a useful tool for the early identification of MWDs that are at risk for ongoing blood loss and decompensatory shock.[9]
• Canines experiencing major trauma may present or become **hypocoagulable**. These trauma-associated coagulopathies are **positively correlated** with the incidence of hemorrhage and transfusion requirements.[14]

Clinical and Diagnostic Considerations for Predicting Transfusion Needs

- Highly consider blood transfusion in MWDs experiencing major trauma that have **evidence of shock** or **worsening anemia** and /or as a requirement for **perioperative hemodynamic optimization**.[3]
  - Clinical signs indicative of hemorrhagic shock vary greatly and are not always readily recognizable; particularly, in the presence of intracavitary hemorrhage (pleural, peritoneal, or retroperitoneal).
  - Early identification of internal hemorrhage remains a challenge without the use of advanced imaging modalities (e.g., focused assessment with sonography for trauma, computed tomography). Casualties with severe internal hemorrhage may succumb to hypovolemic shock before a medical provider realizes the presence and extent of internal bleeding.
  - A hands-on physical examination has a low sensitivity for identifying internal bleeding, particularly, in patients suffering only blunt trauma with no external injuries; however, **despite the absence of external injuries, internal hemorrhage is likely in any casualty suffering major blunt force or penetrating trauma with accompanying signs of circulatory shock (i.e. tachycardia, pale mucous membranes, prolonged capillary refill time, poor femoral artery pulse quality, depressed mentation, cold extremities).**
  - Anatomical injury patterns (thoracic and abdominal trauma) with supportive physical examination findings (e.g. bruising around the umbilicus, distended abdomen with positive fluid wave test, localized pain or tenderness, etc.) may also direct the provider's attention to the most likely areas to explore for sources of internal hemorrhage.

- Remain cognizant of occult hypoperfusion (cryptogenic shock) from ongoing hemorrhage, particularly, in MWDs with blunt abdominal trauma.
  - Although, overt hypotension is the most widely recognized sign of circulatory shock, it is also indicative of more advanced shock.
  - Traditional vital signs (HR and blood pressure) may not always serve as reliable markers of blood loss and decreased perfusion due to rapid activation of compensatory mechanisms.

PCV and TS interpretations

- Serum PCV / TS are specific but insensitive predictors of subsequent transfusion in dogs.

- Trauma patients with severe, acute hemorrhage may require transfusions at **much higher PCVs** than patients with more chronic disease or less systemic compromise.[12]

- In acute hemorrhage, PCV and TS values initially remain within reference intervals due to the loss of red blood cells and plasma in equal proportions. As time elapses, the PCV may initially remain within (or even above) the laboratory reference range while the TP values progressively declines.
- The discrepancy in PCV and TS is subsequent to: a) splenic contraction-induced autotransfusion fostering a normal to high PCV, in conjunction with b) transcapillary fluid shifts from the interstitial to the intravascular space causing a dilutional effect on remaining serum protein concentrations.
- Eventually, both PCV and TS values decrease as hemorrhage and subsequent fluid resuscitation ensues. Declining peripheral PCV/TP values with increasing progressive signs of circulatory shock and increasing body cavity effusion is an indicative finding of ongoing, active intra-cavity hemorrhage.

Clinical and Diagnostic Considerations for Predicting Transfusion Needs
• In the context of trauma, suspect acute blood loss in any polytrauma patient that **presents with a "low, normal or high" PCV and a low TS (≤ 4.5 g/dL).**
• Declining peripheral PCV/TS values with increasing abdominal effusion PCV/TS is supportive of ongoing, active intra-abdominal hemorrhage.
Lactate and BE
• High serum lactate (particularly, 5 mmol/L or greater) in combination with lower PCV and TS concentration is consistent with the need for transfusion[3]:
• BE values -6.6 or lower is supportive of transfusion needs. In canines with blunt trauma, arterial BE may serve as a predictor of mortality and blood transfusion requirements within 24 hours of admission.[12]
• Lactate and BE can be performed on most blood gas analyzers; either arterial or venous blood can be used to determine these values.
• Studies have shown the presence of cryptogenic shock in patients with elevated base excess (BE) or serum lactate level in face of systolic blood pressures at appropriate values.[15]
Diagnostic Imaging
• Survey radiographs in conjunction with a TFAST and AFAST, when available, are recommended diagnostic modalities to include during the primary survey to increase the diagnostic sensitivity of identifying internal hemorrhage. Additionally if available, computed tomography can be utilized as a more sensitive modality to determine extent of traumatic injuries and identification of occult hemorrhage. Clinicians should be aware of the need to not only acquire images in this modality but the need for interpretation of the data that is generated.

• Abdominal fluid score(AFS) in MWDs with traumatic hemoperitoneum:
  • AFS of 1 or 2 are considered small-volume bleeders, these patients rarely become anemic from the intraabdominal hemorrhage.
  • AFS of 3 or 4 are considered large-volume bleeders and are more likely to become anemic and warrant transfusion therapy.[16]

Table 7: Canine Vital Signs - Perfusion parameters based on severity of circulatory shock

Stage of shock	HR*	CRT	MM	Mentation	Pulse Quality	SBP
Normal *(at rest)**	< 120	< 2 s	Pink	Bright, alert	Strong	> 90
Acute Compensatory	> 120	< 1 s	Red	Normal	Fair	> 90
Early Decompensatory	> 140	> 2 s	Pale	Depressed	Weak	< 90
Terminal	< 80	absent	Pale	Obtunded	Absent	Low

**Normal values are for a RESTING state. Exercise/activity, pain, stress will result in higher HRs*

Table 8: Available blood products and indications for use

Product	Components	Indications
Fresh Whole Blood (FWB) *Use within 4 - 6 hours of collection*	• Red Blood cells (RBCs) and White Blood Cells (WBCs) • Plasma proteins[a] • All coagulation factors • Platelets	• Severe, acute hemorrhage • Anemia[c] + Hypovolemia • Anemia + Coagulopathy / ATC / TIC • Severe thrombocytopenia[d]
Stored Whole Blood (SWB) *Stored at 4°C for up to 28 days (depending on anticoagulant)*	• RBC, WBCs • Plasma proteins[a], coagulation factors, platelets (decreased circulation time)	• Severe, acute hemorrhage • Anemia + Hypovolemia • Anemia + Coagulopathy / ATC / TIC
Fresh Frozen Plasma (FFP) • *Frozen at < -18°C within 8 h from collection* • *Good for 1 year*	• All coagulation factors • Plasma proteins[a] • Antithrombin	• Coagulopathy / ATC / TIC • Colloidal volume resuscitation • Hemorrhagic shock as bridge to whole blood replacement
Freeze Dried Plasma (FDP) • *Lyophilized canine plasma* • *Reconstituted with water and then stable for 28 days refrigerated*	Essentially bioequivalent to FFP	• Coagulopathy / ATC / TIC • Colloid volume expander • Hemorrhagic shock as a bridge to whole blood replacement

[a] Plasma proteins include: albumin, globulin, and fibrinogen

[b] Consider **Acute Blood Loss/Hemorrhage** indicated if one or more of the following:
- Estimated or anticipated blood loss > 20% of eTBV, about 400 – 500 mL in a 25 kg MWD. (eTBV in MWD = 85 mL/kg)
- Systemic signs of hypoperfusion. (See Table 1.)
- SBP < 90 mm Hg or drop in SBP by ≥ 30 mm Hg
- Hypothermia (< 99°F or < 37°C)
- Hyperlactatemia (≥ 5 mmoL/L) and / or Base excess -6.6 or lower

[c] **Symptomatic anemia** resulting in:
- Tachycardia (HR ≥ 160 ± 20 beats/minute) ± bounding femoral pulses
- Pale to white mucous membranes
- Depressed mentation
- Presence of worsening anemia with signs of impaired oxygen delivery:
  - Hypoxemia (SpO_2 < 90%, room air)
  - Elevated RR (> 40 breaths/min) with increasing respiratory effort

ATC – Acute traumatic coagulopathy; **TIC** – Trauma-induced coagulopathy

Table 9: Indications for blood products use by condition

Indications	Recommended Component (In Order of Preference)
Anemia • Hypovolemia • Concurrent coagulopathy	Fresh or Stored Whole Blood
Severe, acute hemorrhage	1st: Fresh or Stored Whole Blood 2nd: pRBCs + FFP or (FDP) (1:1 or 1:2 ratio) 3rd : FDP or FFP as resuscitative fluid until whole blood can be administered
Thrombocytopenia (< 15,000) • Presence of spontaneous hemorrhage • Presence of petechial or ecchymosis	1st: Fresh whole blood 2nd: Stored whole blood
Coagulopathy • Idiopathic / inherited **ATC/TIC**	1st: Fresh Frozen Plasma or FDP 2nd: Whole Blood (consider patient volume status)

WHOLE BLOOD TRANSFUSION

Whole blood (WB) is the preferred product for resuscitation of severe hemorrhagic shock in an MWD. Canine WB contains a biologically balanced ratio of all canine blood products and, as such, is the product most likely to restore effective circulating volume and oxygen carrying capacity while preventing coagulation alterations. Any MWD that requires a transfusion subsequent to trauma-induced hemorrhage should receive WB as the product of choice when available.

The primary blood group classification of clinical significance for transfusion in MWDs is based on the dog erythrocyte antigen (DEA) system. Although approximately 13 antigen specificities have been identified, only the DEA 1 system (particularly DEA 1.1) is of most concern due to its high degree of antigenicity and ability to result in an acute hemolytic transfusion reaction. Naturally occurring anti-DEA 1 alloantibodies associated with acute hemolysis (< 24 hours post-transfusion) are not present in canines; therefore, a cross match prior to a MWD's first transfusion is generally not necessary in a naïve recipient.[17]

***Note**: Transfusion of DEA 1-positive blood to a DEA 1-negative MWD will cause the recipient to develop antibodies against the DEA 1 positive antigen; this places the MWD at risk for future transfusion reactions.*

To mitigate the risk of a potential transfusion reaction, the recipient's blood type and previous transfusion history should always be confirmed prior to any transfusion. A crossmatch compatibility should be done for any MWD that has received a previous transfusion ≥3 days prior to their next transfusion or if previous transfusion history cannot be confirmed. See below section on typing and cross matching.

HANDLING/STORAGE

- Fresh WB is collected from a donor and ideally administered to the recipient within 4-6 hours of collection.
- After 6-8 hours, the product becomes stored/chilled WB and should be kept at 4-6 degrees Celsius in a refrigeration device approved for chilled blood product storage.
- The shelf life of canine WB at 4-6 degrees Celsius depends on the anticoagulant used when the blood was collected.
- Canine WB should be stored refrigerated for up to 21 days when collected in CPD and up to 28 days when collected with CPDA-1. *(Note: the 28 day shelf life of canine whole blood is different than the shelf life of human whole blood based on currently available in vitro data on refrigerated canine whole blood.[2])*
- ***WB should never be left at room temperature for longer than 4-6 hours and should never be frozen***.
- When transporting canine WB, ensure that it is packaged in appropriate insulated containers on wet ice to maintain proper temperatures.

DOSAGE

- In most MWDs, a reasonable starting dose for a dogs needing a WB transfusion due to acute blood loss is one 450-500 mL bag (unit) of WB. Goal-directed clinical and laboratory reassessment of MWD should be done after the first bag of WB to determine if more blood is indicated.
  - A rough estimate of 2 ml/kg of WB is required to raise the patient PCV by 1%.
  - The desired target PCV to reach is one that results in sustained improvement of clinical signs and laboratory values for the MWD, usually >20-25%.
  - Simply targeting a normal PCV range may not be necessary and could result in increased risk for undesirable transfusion reactions.
- Transfusions that take longer than 4-6 hours to complete are at risk for bacterial contamination and subsequent adverse effects.
- In a controlled setting involving a hemodynamically stable MWD, start with an initial WB transfusion rate of 0.5 to 1 mL/kg/h for the first 15 minutes and monitor for any adverse transfusion reactions. If no transfusion reactions are observed, increase the rate to provide the remaining amount within 4 hours; recommended WB transfusion rates for normovolemic canines is 5 – 10 mL/kg/h.
- In emergent situations involving severe, acute blood loss leading to trauma-induced hemorrhagic shock, a goal-directed WB transfusion rate of up to 20 mL/kg/h or 1.5 mL/kg/min over 20 minutes can be administered to restore hemodynamic stability.
- Reassess the MWD after the first unit of WB to determine if a subsequent transfusion needed.

ADMINISTRATION

- When possible, chilled WB should be passively warmed to room temperature over 30-60 minutes prior to administration, or passed through an IV infusion line warmer during administration. A gravity drip with an in-line adult human 170-260 micron filter set is recommended for the administration of canine WB to an MWD unless a blood specific infusion pump is available; WB should not be run through a standard fluid pump in order to preserve the structure of the donor RBCs.[18,19]
- Administration to the MWD patient should occur through either a dedicated, large-bore (18 gauge or larger) peripheral or central intravenous catheter or an intraosseous catheter within a span of 4 hours. No other

fluid therapy or medication administration should occur simultaneously through the same catheter supporting a WB transfusion.

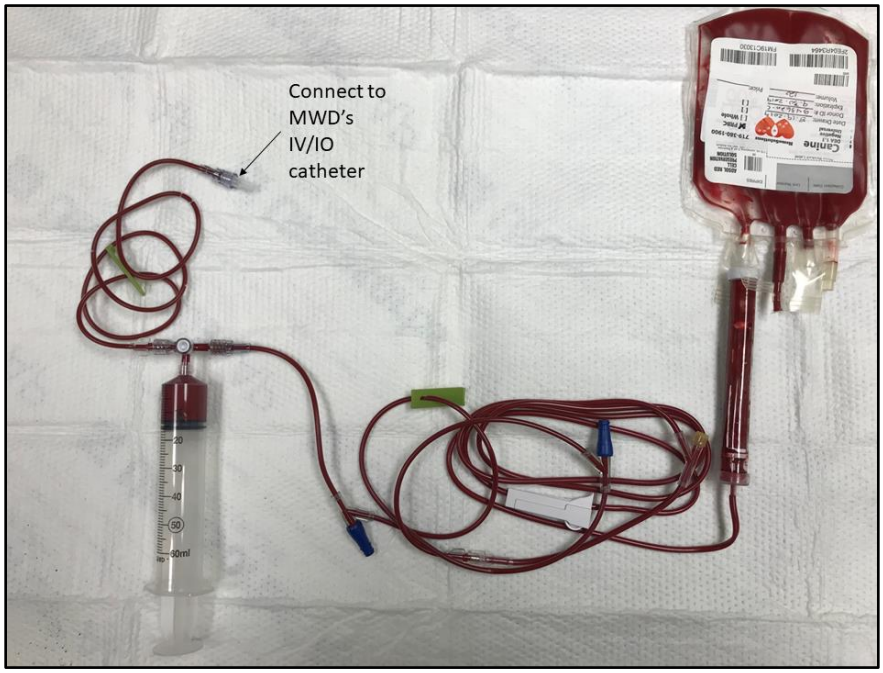
- Administration of WB by gravity flow is recommended in canines. In order to preserve the integrity of donor RBCs,[20] it is not recommended to administer WB through an infusion pump unless the pump and administration set are designed and validated for use with blood or other blood component (pRBCs, plasma, albumin, platelets).
- Transfusions that take longer than 4-6 hours to complete are at risk for bacterial contamination and subsequent adverse effects.
- In emergent situations, canine WB can be transfused rapidly to maintain effective circulating volume, oxygen carrying capacity and to prevent cardiovascular collapse. This can be accomplished by one of the below methods:

1. Manually squeezing the bag of whole blood or by placing the bag of whole blood in a pressure sleeve.

OR

2. Employ a rapid transfusion set (See Figure 1 below.)
    a. Spike the blood bag with a standard blood administration set.
    b. Connect a 3-way stopcock to the administration set and then connect a 60 mL syringe and an extension set to the 3 way stopcock.
    c. Pull blood from the bag into the 60 mL syringe and prime the line and the extension set.
    d. Ensure any air is removed from the circuit and connect the extension set to the MWD's catheter.
    e. WB can then be rapidly pushed from the syringe to the MWD and refilled from the bag without disconnecting the set.

Figure 1. Example of WB set up for rapid infusion



Transfusion monitoring and reassessment

1. Measure and record baseline values of vital signs and perfusion parameters prior to the start of the transfusion. Values to measure include: rectal temperature, heart rate, pulse rate and quality, respiratory rate, mucous membrane color, capillary refill time, and blood pressure (if equipment is available).
2. Reassess vital signs:
    a. Every 5 minutes for the first 15 minutes, then
    b. Every 15 minutes for the first hour, then
    c. Every 30-60 minutes until completion of the transfusion.
3. Capture a final set of vital signs at the conclusion of the transfusion.
4. Re-evaluate a PCV and TS one to two-hour post-transfusion.

Transfusion reactions

- Transfusion reactions of concern with canine WB transfusions include acute hemolysis, allergic/anaphylactic hypersensitivity, febrile non-hemolytic, and delayed hemolysis. (See Table 10 below.)
- Supportive treatment should address the type and severity of the reaction, but in all cases the transfusion should be stopped immediately to allow for further assessment of the patient and donor bag before continuing.
- For mild reactions, decreasing the transfusion rate (typically decrease the rate by 50%) may be all that is needed to avoid further issues. If signs of transfusion reaction persist or worsen, the transfusion should be halted and the supporting 64F should be consulted.

***Note**: A 64F is a veterinary clinical specialist typically found at the veterinary unit co-located with the human Role 3 and higher facilities. A 64F can also be reached via the ADVISOR Trauma Care Helpline, Option #5.*

Table 10. Transfusion reactions[19]

Transfusion Reaction	Clinical Signs
Acute Hemolytic Reaction Result of recipient immunological reaction to donor red cell antigens	• Fever • Weakness, tremors • Salivation, vomiting and/or elimination • Agitation, vocalization • Tachycardia, arrhythmias • Tachypnea, dyspnea • Hypotension • Hemoglobinemia • Hemoglobinuria
Delayed Hemolytic Reaction Result of recipient immunological reaction to donor cell antigens	• Clinically less severe Acute Hemolytic Reaction • Occurs >2 days post-transfusion

Transfusion Reaction	Clinical Signs
Febrile, Non-Hemolytic Reaction Result of white cell antigens and other bioactive substances in donor blood	• Temperature increase of >1° Celsius (~2°Fahrenheiht) • Vomiting • Tremors • Resolution in 1 to 12 hours
Hypersensitivity Transfusion Reaction Result of recipient IgE-mediated reactions to donor gamma globulins	• Mild to severe urticaria • Mild to severe angioedema and erythema • Anaphylaxis, bronchoconstriction and effusions in severe cases • Typically no fever expected • Can occur within minutes to hours of starting
Pre-Transfusion Hemolysis Result of improper storage or handling of donor blood, or bacterial contamination	• Signs will mimic Acute Hemolytic Reaction
Transfusion Related Circulatory Overload (TACO) Related to large volume and massive transfusions	• Hypocalcemia from citrate intoxication • Tremors and seizures • Arrhythmias • Dilution thrombocytopenia or coagulopathy • Hypomagnesemia • Acid-base disturbances • Hypothermia
Transfusion-Related Acute Lung Injury (TRALI) Rare in canines	• Tachypnea, tachycardia and respiratory distress related to development of non-cardiogenic pulmonary edema

FRESH FROZEN PLASMA TRANSFUSIONS

Canine FFP is canine WB that is separated from its cellular components and frozen within 8 hours of collection. FFP can be stored frozen for up to one year which then is relabeled as frozen plasma (FP). FFP contains all coagulation factors and plasma proteins found in circulating blood. FP contains most of the coagulation factors but loses the labile factors (FV, FVIII, von Willebrand factor) over time.

USES

- FFP is indicated to correct coagulation factor deficiencies and or prophylactically to treat MWDs who are at risk of bleeding from clotting factor abnormalities.
- As compared to isotonic crystalloids, canine FFP provides the following added benefits as a resuscitation fluid:

- Supports hemostatic resuscitation. Its ability to deliver coagulation factors and other plasma proteins (e.g. albumin, fibrinogen) while restoring intravascular volume minimizes the risk of invoking a dilutional coagulopathy.
- Provides oncotic support by supplementing albumin in addition to restoring effective circulating volume.

AVAILABILITY

- FFP comes in different sized units but 240 to 250 mL units are most appropriate for MWDs.
- FFP is obtainable from one of two methods:
  1. Separation of Fresh Whole Blood (FWB):
     - Place a unit (450 to 500 mL) of FWB into a blood centrifuge and spin at 2000 x g for 10 minutes to separate the cellular components.
     - Express the plasma from the primary collection bag into a satellite bag and then seal.
     - Place plasma in freezer at -20°C to -80°C (-4°F to -112°F) within 8 hours of collection if it is intended to serve as FFP.
  2. Plasmapheresis is an alternate way to obtain FFP; however, this process requires special training and equipment. Only trained personnel with the appropriate equipment should perform plasmapheresis.

HANDLING/STORAGE

- FFP should be stored in a dedicated, appropriate freezer at -20 to -80°C. Perform daily temperature checks to ensure the freezer is secured and operating appropriately.
- If FFP is to be shipped it should be shipped with proper insulated packaging on dry ice to ensure the product remains frozen at the correct temperatures.

***Note**: Care should be taken when handling FFP as the plasma bag is not pliable and can crack at low temperatures. Consider placing in two large Ziploc® bags or similar packaging to avoid direct handling of the FFP bag.*

DOSAGE AND ADMINISTRATION

- Typical dose of canine FFP is 10 to 20 mL/kg over 1- 4 hours (depending on the situation). This translates to approximately one to two 240 to 250 mL bags of FFP per MWD.
- FFP should NOT be used to try to increase plasma albumin levels as up to 40 to 50 mL/kg could be necessary to raise recipient's albumin levels by 1.0 g/dL.
- MWDs that do not have ongoing hemorrhage or other substantial fluid losses, administration of FFP over 2-4 hours is appropriate.
- FFP must first be thawed before administration.
  - Optimally, thaw FFP in a commercial plasma thawer following manufacturer's recommendations for thawing human plasma.
  - If no plasma thawer is available, remove FFP from the freezer and place in two Ziploc® bags. Submerge the FFP and outer Ziploc® bags in lukewarm tap water. A large MWD food bowl is often suitable for this purpose.

- Ensure the water does not exceed 98.6°F (37°C); water temperatures exceeding 98.6°F (37°C) may cause protein denaturation. It is important that the thawing process does not occur too quickly by adding hot water as plasma proteins can be denatured if the process is rushed. Consider exchanging the water every 15 to 20 minutes or use a gentle continuous flow of water if necessary to keep the water bath warm. Expect 30-40 minutes to complete the thawing process using this technique.
- Once thawed, spike FFP bag with a blood administration set (which contains a 170 micron blood filter) or a regular fluid administration set. If no blood administration set is available, place a blood filter (Hemo-Nate® filter) in the transfusion line to reduce transfusion of clots or other impurities from the transfused product. Do not let the lack of a Hemo-Nate® (or similar blood filter) preclude the administration of FFP if it is clinically necessary.
    1. Connect the primed transfusion line to a 20 gauge or larger bore peripheral or central IV catheter or an IO catheter.
    2. Begin transfusion at 1 to 2 mL/kg/h over the first 15 minutes and monitor the MWD for signs of transfusion reaction. (See Table 10.) If there is no significant reaction, increase the rate of transfusion to 2 to 4 mL/kg/h for an additional 15 minutes. If no transfusion reactions are seen over the first 30 minutes, increase the transfusion rate to ensure the complete delivery of FFP within 2 to 4 hours.

- In emergent situations, consider blousing 1-3 units thawed FFP to MWDs similar to that indicated for MWDs that are rapidly losing blood form a major blood vessel laceration. Bolus the whole unit of FFP over 10 minutes by one of the following techniques:
    - Placing the FFP bag in a commercial IV pressure infuser system or manual squeezing of the FFP bag, OR
    - Using the 3-way stopcock and 60 mL syringe set-up described in the WB administration section above.

Transfusion monitoring and reassessment

- Vigilant monitoring for transfusion reactions is required during non-emergent FFP transfusions (e.g. in absence of bolus FFP therapy). Types and signs associated with transfusion reactions are similar to those for WB transfusions. (See above section on transfusion reactions for WB.)
- Monitor core body temperature, pulse rate and quality, respiration (rate and effort) and blood pressure:
    - Every 5 minutes for the first 15 minutes of transfusion, then
    - Every 15 minutes for the first hour, then
    - Every 30-60 minutes thereafter until completion of the transfusion.
- The most common indications of a transfusion reaction are fever, facial edema, tachycardia, tachypnea, vomiting, hypotension and weakness.[7]
    - If any of these signs are encountered, reduce the transfusion rate by 50% and reassess the MWD. If clinical signs resolve, continue the transfusion.
    - If signs of transfusion reaction persist or worsen despite reducing the transfusion rate, halt the transfusion and seek consultation with the supporting 64F.
- Reassess the MWD upon completion of the transfusion. Assessment includes a physical examination with special attention to the cardiovascular, coagulation and perfusion parameters to include blood pressure assessment. If end points of resuscitation are not reached, consider administering an additional unit of FFP following the guidelines above.

- Continue hemorrhagic shock resuscitation with FDP or FFP until canine WB is available to administer.

FREEZE DRIED PLASMA

Canine Freeze Dried Plasma (cFDP) can be used in lieu of FFP for any of the above-mentioned indications cited for FFP. In addition, since cFDP can be reconstituted quickly (does not require a thawing process), it is possible to start a transfusion more rapidly as compared to FFP. When available, strongly consider cFDP as a resuscitation product at the point of injury, en route to Role 2 or 3 care and/or until canine WB becomes available. cFDP replaces effective circulating volume without diluting coagulation factors or substantially reducing oncotic pressure. In this way, cFDP's most beneficial role on the battlefield is to serve as bridge to resuscitation with canine WB. Evidence supports that cFDP is biologically equivalent to FFP in terms of coagulation factor activity, biochemical profile and clot forming ability (Edwards – unpublished data).

HANDLING/STORAGE

- cFDP is available as a white to yellow powdered product within a transfusion bag that is enclosed in a Mylar outer wrap. To minimize any transfer of moisture from the environment into the product, do not open the Mylar wrap until the product is ready for use.
- Store cFDP at room temperature or refrigerated at 2 to 6°C (35.6 to 39.2°F).

RECONSTITUTION

Follow the manufacturer's directions in the reconstitution of cFDP. In general, sterile water for injection (amount specified by the manufacturer) is aseptically added through either an inserted port or the designated port provided on the bag of cFDP. Gently manually mix the bag until the product completely dissolves (approximately 5 minutes). Once reconstituted, either transfuse within 4 hours of reconstitution or refrigerate for up to 28 days.

DOSAGE

- MWDs in need of a plasma transfusion should typically receive one 240 to 250 mL bag (unit) of cFDP; reassess after the first unit to determine if the MWD requires subsequent transfusions.
- The speed of administration depends on the indication and clinical condition of the MWD.
    - For MWDs that do not have ongoing hemorrhage or other substantial fluid losses, administration of FDP over 2 to 4 hours is typically appropriate.
    - In emergent situations, bolus FDP as indicated for MWDs that are rapidly losing blood. Boluses of 1-3 units may be necessary to stabilize a severely injured MWD. To accomplish this, a unit of FDP may be placed in a commercial pressure infuser sleeve or can be accomplished by using the 3 way stopcock and 60 mL syringe set up described in the WB administration section above.

ADMINISTRATION

- If the bag of FDP has an inline filter, attach extension sets to the inline filter port and prime the line with FDP to remove the air. If no inline filter is present, spike the bag of FDP with either a:
  - Blood administration set (that contains a blood filter), OR
  - Regular fluid administration set that has a separate blood filter (such as a Hemo-Nate® filter) placed in the transfusion line.

  ***Note**: Although an in-line filter is recommended to reduce clots or other impurities from the transfused product, the lack of a blood filter does not preclude the administration of FDP if the transfusion is clinically necessary.*

- Connect the primed transfusion line to a 20-gauge or larger peripheral or central IV catheter or an IO catheter.
- Begin transfusion at 1 to 2 mL/kg/h over the first 15 minutes and monitor for signs of transfusion reaction (see below). If no significant reaction observed, increased the rate of transfusion to 2 to 4 mL/kg/h for an additional 15 minutes. If no transfusion reactions observed over the first 30 minutes, increase the transfusion rate to ensure delivery of the FDP unit is complete within 2 to 4 hours.

TRANSFUSION MONITORING AND REASSESSMENT

Transfusion monitoring and assessment in the administration of FDP is the same as for FFP detailed above.

BLOOD DONATIONS (WALKING BLOOD BANKS)

When canine WB is not available and is needed for a critically injured or ill MWD, blood can be collected from other canines for donation. U.S.-based MWDs are the recommended first-choice for walking-blood donors, since the U.S. Army Veterinary Corps knows that these canines are well-cared for, healthy, up-to-date on all major vaccinations and preventative medications, and clear of blood-borne infectious diseases. If a U.S.-based MWD is not available, consider a US based contract working dog as an alternative donor. Due to the high risk of disease transmission, NEVER use an indigenous canine as a blood donor. An ideal MWD to select for further screening is a canine that has never received a prior transfusion of any blood product (to include plasma products), weighs over 60 pounds (27 kg), are deemed healthy (based on physical examination), and not receiving any medication other than standard preventive medications (heartworm, flea and tick).

SCREENING[21]

- If not previously known or performed, use a commercial DEA-1 blood-type kit to determine the blood type of the potential MWDs (see below section on typing and cross matching).
- Screen ALL canines for infectious diseases caused by Dirofilaria immitis, Borrelia burgdorferi, Ehrlichia canis, Ehrlichia ewingii, Anaplasma phagocytophilum, Anaplasma platys, Leishmania utilizing in-house diagnostic tests.
- Obtain a minimum database (complete blood count, serum chemistry profile, urinalysis, and fecal floatation) to assure that no underlying conditions are present that precludes donation.

- MWDs that are negative for infectious diseases and have no significant abnormalities noted on their minimum database are considered acceptable donors unless other extenuating circumstances deem the donor not acceptable.

***Note**: In an emergent situation when time is critical, it is reasonable to consider any healthy MWD as a blood donor even if they have not had the aforementioned screenings.*

BLOOD COLLECTION

- Do not collect blood from donors more frequently than every two months.
- Do not work or fly (via fixed wing aircraft) a donor for 24 hours following a donation to allow recovery from donation.
- Consider administering intravenous isotonic crystalloids to a donor following blood collection as needed to replace the volume donated.

Anticoagulants.

Recommend the use of CPDA-1 (citrate phosphate dextrose adenine). CPDA-1 results in the longest blood shelf life at 28 days for canine WB. If CPDA-1 is not available, collect WB into bags containing CPD.

***Note**: Canine WB anticoagulated with CPD results in a recommended shelf-life of up to 21 days when properly stored at 6°C (+/- 2°C). Approximately 1 mL of anticoagulant is used per 9 mL of blood collected from a dog*.
Caution**: **Accidental intravenous injection of undiluted citrate anticoagulants may cause cardiac arrest.

Sedation

- Always take the MWD's temperament into consideration prior to administering any sedatives. Although most MWDs require sedation in order to keep them still to facilitate blood collection, not all MWDs require the same levels of sedation.
- For most MWDs, consider the following initial protocol:
  - Butorphanol (0.1 – 0.4 mg/kg IV/IM) combined with,
  - Midazolam (0.25 – 0.5 mg/kg IV/IM).

  If butorphanol is not available consider hydromorphone (0.05-0.1 mg/kg) IV/IM combined with Midazolam

  Considering the average size MWD weighs approximately 30 kg, consider the following doses as acceptable for initial sedation in situations when a MWD's weight is unknown and/or not obtainable:

  - Butorphanol (3 to 12 mg IV/IM) OR hydromorphone 1.5-3 mg IV/IM combined with,
  - Midazolam (8 to 15 mg IV/IM).

***Note**: Most MWD Handlers have a weight-based MWD drug card that includes drugs doses that are specific to their MWD. Check for this card prior to making any weight-based drug calculations.*

  - Some MWDs may require heavier sedation to facilitate blood collection and avoid complications such as damage to the blood vessel (aka. blown vein) leading to contamination and/or insufficient collection. For these cases, consider adding ketamine (2 to 4 mg/kg IV/IM) to the above listed protocol.
  - AVOID the following drugs in the sedation protocol:

1. Acepromazine: May influence platelet function; therefore, is not recommended in situations that warrants active platelets.

2. Dexmedetomidine: May causes clinically significant bradycardia and peripheral vasoconstriction, which interferes/hinders blood flow and collection.

Procedure

- Employ aseptic technique
  1. Wash hands with soap and water prior to the procedure and don sterile gloves.
  2. Clip and surgically prepare the area over the external jugular vein.
- Do not allow air to enter the blood collections system. Most commercial blood collections systems designed for humans possess an in-line device that prevents air from entering the line. If not using a human-designed commercial blood collection system, consider the following to prevent air from entering the system.
  1. Clear the collection line of air by turning the bag upside down, removing the needle cover and allowing a few drops of anticoagulant to exit the needle.
  2. The collection line is then immediately clamped and not released until the venipuncture has been accomplished.
- Using a standard human tri or quad commercial blood donation bag set, sterilely insert the attached needle into the left or right external jugular vein. Once inserted, the in-line cannula is broken to allow the flow of blood to begin.
- Utilize a balance or gram scale for collection. Prior to collection, tare the scale with the collection bag to "Zero".
- Blood is collected by gravity flow into a standard 500 mL CPD or CPDA-1 blood bag to the appropriate volume.
  1. Place the MWD in lateral or sternal recumbency. If the MWD is in lateral recumbency, place a towel underneath the neck in order to facilitate obtaining and preserve venipuncture of the jugular vein.
  2. Place the collection bag on the floor or at a location lower than the MWD.
- Ensure the ratio of blood collected to anticoagulant is exact to assure an appropriate level of anticoagulation as well as to maximize cell viability:

  The specific ratio is 450 mL blood +/- 10% (i.e. 405 mL to 495 mL) per 63 mL of anticoagulant (CPD or CPDA-1).
- Gently rock the bag during collection to insure adequate mixing of the blood and anticoagulant.
- Discontinue collection when the total weight of the blood collected is 430 to 450 grams.
- At the end of collection:
  1. Clamp or tie off the line before removing the needle from the vein; this prevents air from entering the bag before all the blood has cleared the walls of the line.
  2. Remove the needle from the vein and apply appropriate pressure to the venipuncture site for at least 5 minutes to prevent further bleeding.

- After the collection line is tied or clamped, use a tube stripper to "strip" the blood left in the line into the bag.
    1. Gently rotate the bag to mix the blood and anticoagulant;
    2. Invert the bag and allow the line to refill.
    3. Repeat four to five times to assure thorough mixing of the blood in the line with the anticoagulant in the bag.
- When collecting WB, satellite bags should be removed using heat sealers or clamps leaving only the collection bag containing WB.
    1. The line is then heat sealed, clamped or tied in segments for use in future cross-matches.

    ***Note**: The line has a series of numbers printed on the surface that correspond to segments. Fill the line, then use the heat sealer to separate it into appropriate segments (approximately 6 to 8 segments) or 'pigtails'. These "pigtails" are used for cross-matching.*

    2. Heat seal the line then cut the needle from line and discard the needle according to safety procedures.
- Mark the outside of the bags with: collection date, donor's name, weight of the bag, and PCV of the donor. Make three labels – one for the transfusion sheet, one to remove and place in the inventory log book, and one to stay on the bag.
- Store fresh WB upright in a designated refrigerator, with a temperature record maintained daily and recorded on the outside of the refrigerator.

Table 11. Supplies needed for MWD blood donation

Donor Screening Supplies	Sedation Supplies (If Needed)	Collection Supplies
• Syringes, needles, and tubes for blood and urine collection • Leishmania tests –(if in endemic area) (NSN 6640-NCM093803) • Idexx SNAP 4Dx Plus tests (NSN 6550-016504412) • Canine blood typing cards - Rapid Vet (NSN 6550-016479167) • CBC, Chemistry, UA, and Fecalyzer	• Atropine sulfate • Butorphanol • +/- Midazolam +/- ketamine • Syringes, needles, calculator	• 4x4 gauze sponges • Sterile scissors • Sterile draping cloth • Sterile gloves • Whole Blood Collection Bags (CPD or CPDA-1) • Balance or gram scale • Strippers • Metal clamps or heat sealer
Supportive Care Supplies	**Aseptic Prep Supplies**	**Crossmatch Supplies (Optional)**
• 18 G IV Catheter supplies • Crystalloid fluids 1 liter (x 2) • Primary IV set • Pressure infusion bag or fluid pump • Vitals Monitor	• Clippers • Rolled towel to support neck • Exam Gloves • Chlorhexidine or betadine surgical scrub • Sterile gauze • Sterile saline or Alcohol	• 0.9% saline • 3 mL test tubes • Pipettes • Centrifuge • Agglutination viewer lamp (optional, microscope also works)

TYPING/CROSSMATCHING OF MWDS

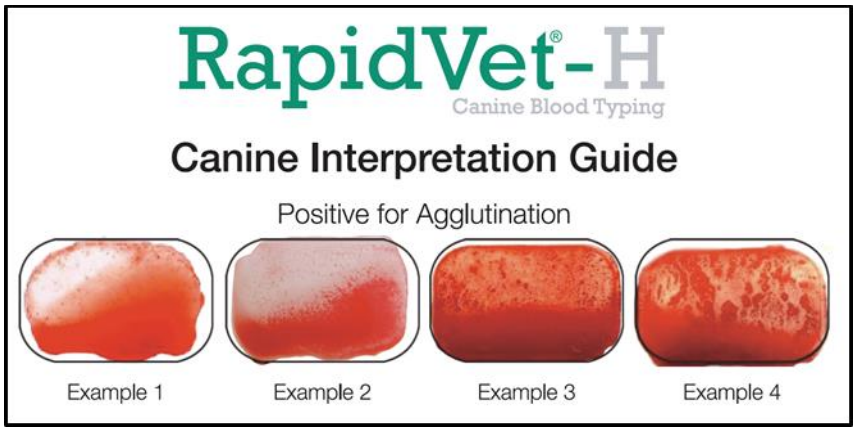
MWDs or other CWDs operating in a deployed environment may or may not have their blood type identified prior to deployment. Identification of a canine's blood type during deployment and prior to transfusion is always recommended but might not be possible unless commercially available blood typing kits (See Figure 2.) are fielded at a Role 2 or Role 3 Veterinary Facilities. For reasons explained below, naïve canines that have never received a prior blood product transfusion can safely receive blood transfusions for a short period of time prior to both typing and cross-matching, if necessary.

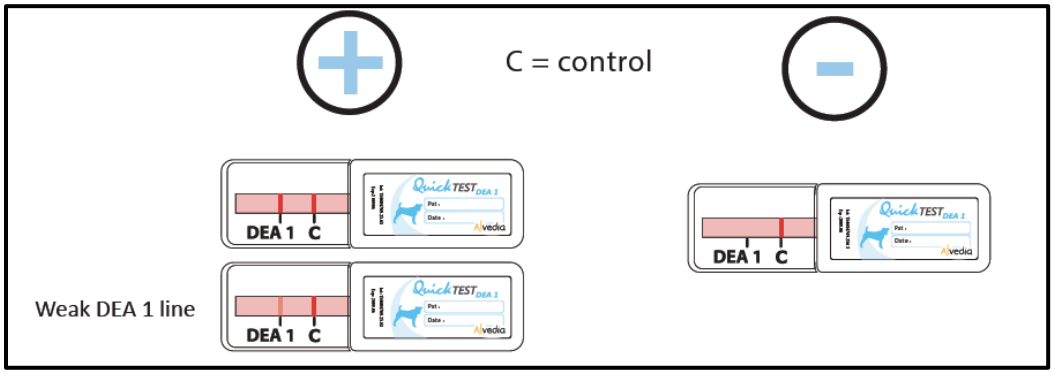
The most commonly tested and reported blood type in canines is DEA 1. In addition to DEA 1, there are 12 other DEA blood types that are based on antigenic surface markers of the canine erythrocyte.[22] Generally speaking, only the presence of the DEA 1 antigen has historically resulted in clinically relevant transfusion reactions in dogs. As a result, most commercially available blood typing kits screen specifically for the presence (DEA 1 positive) or absence (DEA 1 negative) of the DEA 1 antigen. MWDs and other operational canines will therefore have a blood type reported as DEA 1(or with the older naming convention DEA 1.1) positive or negative if they have been previously blood typed. Although DEAs could theoretically cause transfusion reactions, there is no evidence in the veterinary literature to support routine screening of these antigens.

It is important to note that canines do not typically have naturally circulating alloantibodies to the DEA 1 antigen. Therefore, it is possible to transfuse non-typed canine blood products into another MWD and not experience a transfusion reaction – giving rise to the adage that "the first transfusion is free." In practice, the veterinary personnel and other HCPs in theater can emergently provide blood products to MWDs without knowing the blood type of the MWD during the first 72 to 96 hours of care. However, dogs will develop alloantibodies to the DEA antigens 5 to 7 days post-transfusion and should be cross-matched 72 hours after receiving the first transfusion.

Popular, commercially available blood typing kits include point-of-care kits made by RapidVet® and Alvedia (Figure 2). Both kits are simple, inexpensive, and easy-to-use. However, the user should be advised that erythrocyte auto-agglutination can affect interpretation of the RapidVet® test kit. If erythrocyte agglutination is present, a cell washing step is required prior to using the typing cards. The Alvedia test kit is unaffected by cell agglutination due to its patented membrane technology embedded in the testing cartridges.

Figure 2. Examples of Common Blood Typing Kits.





All MWDs should be cross-matched if 72 hours have elapsed since its first transfusion or if any previous transfusion resulted in a transfusion reaction. Crossmatching is the process by which donor and recipient blood are assessed for compatibility and thus reduces the likelihood of a transfusion reaction.

There are two types of cross-matching: **Major** and **Minor.**

1. **Major Crossmatch:** Recipient's serum is mixed with a suspension of the donor's red blood cells. A major crossmatch detects antibodies present in the recipient's serum that will react to antigens present on the donor red blood cells.

2. **Minor Crossmatch**: Recipient's red blood cells are mixed into the donor's serum. A minor crossmatch detects antibodies present in the donor's serum that will react to antigens present on the recipient's red blood cells.

Performing a cross-match is accomplished using either a/an:

1. Commercial cross-matching test kit:

   RapidVet® provides a testing kit called the RapidVet®-H Companion Animal Crossmatch Test for both major and minor crossmatching. The procedure involved in this kit is very similar to traditional laboratory based crossmatching and personnel should refer to manufacturer's directions for the proper employment of the test kit. The advantage in using the RapidVet® kits is that the gel-impregnated kits

used to do the final assessment prevent artifact if naturally occurring red blood cell auto-agglutination is present.

2. In-house, field-expedient procedure described below in Table 12. Equipment required:
   - Small centrifuge
   - Image result for Ethylenediaminetetraacetic acid (EDTA)
   - EDTA-impregnated blood collection tubes (purple top)
   - Non-serum separator blood collection tubes (red top)

Table 12. Field-Expedient Crossmatch Procedure.[23]

Field-Expedient Crossmatch Procedure	
1	Collect EDTA (purple top) blood samples from both the donor and recipient dog.
2	Centrifuge at 5000 x G for 5 minutes
3	Separate plasma from the purple top tubes and decant into red top tubes labeled “plasma.”
4	Place remaining suspension of RBCs in red top tubes labeled “RBCs.”
5	Fill RBC tubes with 2.5 mL sterile saline. Mix gently and centrifuge for 1 min @ 5000 x G.
6	Decant saline and repeat process 3 times to wash the cells of proteinaceous debris.
7	Resuspend RBC pellet with 2.5 mL of saline.
8	**Major Crossmatch**: 2 drops of plasma from recipient placed into a new red top tube with 1 drop of RBC solution from the donor.
9	**Minor Crossmatch**: 2 drops of plasma from donor dog placed into new red top tube with 1 drop of RBC solution from recipient.
10	**Recipient Control**: 2 drops of recipient plasma with 1 drop of recipient RBC solution in new red top tube.
11	All solutions are mixed gently and incubated for 20 min @ 37C.
12	Centrifuge solutions for 15 seconds.
13	Inspect tubes for macroscopic appearance of cell agglutination. Presence in either of the crossmatch solutions indicates incompatibility. Presence in the control tube indicates auto-agglutination and voids any further interpretation of cross-matching results with this procedure.
14	Place one drop on a slide with coverslip and inspect for microagglutination. If present, add a single drop of saline to confirm agglutination. Score agglutination as follows: 4+ = Single solid clump of cells 3+ = Several solid clumps of cells 2+ = Multiple small clumps of cells with cell/debris-free background 1+ = Hemolysis with no visible agglutination. NEG = No hemolysis or agglutination present.
15	Blood is deemed fully compatible with NEG results. However, in practice 1+ agglutination score is generally compatible and safe for a transfusion.

INTRODUCTION

This Role 1, prolonged field care (PFC) guideline is intended to be used after Tactical Combat Casualty Care (TCCC) Guidelines when evacuation to a higher level of care is not immediately possible. A provider of PFC must first be an expert in TCCC. This clinical practice guideline (CPG) is meant to provide medical professionals who encounter traumatic brain injury (TBI) in austere environments with evidence-based guidance. Recommendations follow a "best, better, minimum" format that provides alternate or improvised methods when optimal hospital options are unavailable. A more comprehensive guideline for TBI management is available in the Joint Trauma System Clinical Practice Guideline for Neurosurgery and Severe Head Injury at https://jts.health.mil/index.cfm/PI_CPGs/cpgs.

TBI occurs when external mechanical forces impact the head and cause an acceleration/deceleration of the brain within the cranial vault which results in injury to brain tissue. TBI may be closed (blunt or blast trauma) or open (penetrating trauma).[1] Signs and symptoms of TBI are highly variable and depend on the specific areas of the brain affected and the injury severity. Alteration in consciousness and focal neurologic deficits are common. Various forms of intracranial hemorrhage (ICH), such as epidural hematoma, subdural hematoma, subarachnoid hemorrhage, and hemorrhagic contusion can be components of TBI. The vast majority of TBIs are categorized as mild and are not considered life threatening; however, it is important to recognize this injury because if a patient is exposed to a second head injury while still recovering from a mild TBI, they are at risk for increased long-term cognitive effects. Moderate and severe TBIs are life-threatening injuries.

Prompt evaluation and intervention are necessary to reduce disability and mortality. Rapid evacuation and neurosurgical evaluation, while desirable, are not always feasible in austere environments. Nevertheless, recent data from the conflicts in Iraq and Afghanistan have shown improved mortality among military TBI casualties when compared with similar, propensity score–matched civilian TBIs. This is due partly to the aggressive resuscitation that began at the point of injury.[2] PFC providers, therefore, should be prepared to use resources at hand for aggressive medical management in these patients until additional medical and surgical assets can be made available.

Regardless of mechanism, two categories of injury occur with TBI: primary and secondary. Primary injury occurs at the time of injury and results in irreversible damage to brain tissue.

There are no effective treatments for primary injury. Secondary injury, in contrast, occurs as a result of a complex inflammatory cascade that results in rapid development of brain swelling, rise in intracranial pressure, and subsequent decrease in cerebral perfusion. When severe, this can lead to massive swelling, compression of the brainstem, and, ultimately, death. Thus, the primary focus of TBI management is on limiting the effects of secondary brain injury. The brain possesses minimal cellular oxygen reserve and, therefore, is highly dependent on a continuous supply of oxygenated blood. A systolic blood pressure (SBP) <90mmHg or oxygen saturation via pulse oximetry (SpO_2) <90% more than doubles the risk of death from brain injury.[3] The management of hypotension, hypoxia, hypocarbia or hypercarbia, hypoglycemia, and signs of elevated intracranial pressure (ICP) is essential.

Telemedicine – Management of TBI is complex. Establish a telemedicine consultation as soon as possible.

NEUROLOGIC ASSESSMENT

Goal: Rapidly identify the clinical signs and symptoms of TBI and associated traumatic injuries and assess TBI severity.

Track the progression of brain injury over time and be vigilant for the early signs of rising ICP: worsening headache, focal neurologic deficits and declining neurologic examination.

- **Primary survey**: Perform a rapid trauma survey to assess all injuries. Determine and record the Glasgow Coma Scale (GCS) score (Table 1 below). Assess pupils and motor function in all four extremities.
- **Secondary survey**: After stabilizing any immediate life-threatening injuries, assess for TBI red flags that may indicate moderate to severe head injury (Table 2 below), and perform an initial detailed neurologic examination. See Appendix A for further details on performing a neurologic examination. Annotate findings on the PFC flowsheet.
- **TBI severity classification** using the GCS score[4]:
  - Mild: 13–15
  - Moderate: 9–12
  - Severe: 3–8

Table 1. *Glasgow Coma Scale*

Eye Opening	Verbal Response	Motor Response
4 – Spontaneous 3 – To verbal command 2 – To painful stimuli 1 – No response	5 – Oriented 4 – Confused 3 – Inappropriate words 2 – Incomprehensible sounds 1 – No response	6 – Obeys commands 5 – Localizes to painful stimuli 4 – Withdraws from pain 3 – Flexion to pain 2 – Extension to pain 1 – No response

Table 2. *Features Indicative of Moderate to Severe Head Injury*

Red Flags
Witnessed loss of consciousness
Two or more blast exposures within 72 hours
Unusual behavior or combative
Unequal pupils
Seizures
Repeated vomiting
Double vision or loss of vision
Worsening headache
Weakness on one side of the body
Cannot recognize people or disoriented to place
Abnormal speech

Neurologic Assessment Note

An emerging technology that can be considered as an adjunct to neurologic assessment is ultrasound measurement of optic nerve sheath diameter (ONSD). If the patient is unconscious (i.e. does not follow commands or open eyes spontaneously), measure a baseline ONSD. There is no definite diameter that is diagnostic of increased ICP; however, an ONSD >5.2mm, especially if it increases over time, may indicate elevated ICP.[5] In no circumstance should measurement of ONSD take priority over a neurologic examination, and all results must be considered in the context of the neurologic examination and overall patient status. See Appendix B for further details on using ultrasound to obtain and interpret ONSDs.

ONSD should NOT be attempted in any patient who has sustained an open globe injury where any pressure on the globe is contraindicated. As many as 30% of head injuries in combat may also have an eye injury.[6]

MONITORING

Goal: Prevent secondary brain injury by maintaining adequate oxygenation and ventilation, avoiding hypotension, observing for signs and symptoms of elevated ICP, and trending the response to resuscitation. Detect changes in vital signs and neurologic examination as early as possible.

- **Minimum**: Blood pressure cuff, stethoscope, pulse oximeter, method to monitor urine output. If an advanced airway is in place, monitor $EtCO_2$ with capnometer. Check pupillary response and GCS as often as possible. Document vital signs, GCS score, and urine output on the PFC Casualty Card available at https://prolongedfieldcare.org.
- **Best**: Portable monitor providing continuous vital-signs display, Foley catheter to monitor urine output. If an advanced airway is in place, monitor end-tidal carbon dioxide ($EtCO_2$) with capnography. Check pupillary response and GCS score every hour. Document vital signs, GCS, and urine output on the PFC Casualty Card available at https://prolongedfieldcare.org.

ASSESSMENT AND MONITORING NOTES

- Perform an initial assessment according to TCCC/MARCH (Massive hemorrhage, Airway, Respirations, Circulation, Head injury/Hypothermia) algorithms.
- Severe head injury is associated with additional trauma in 60% of patients.[7]
- If ONSD is used to evaluate for increased ICP and response of ICP to interventions, repeated ultrasound examinations should be performed if there is any change in neurologic examination and at regular intervals (30 minutes) after performing ICP-lowering interventions.
- When possible, a pocket ophthalmoscope can be used to assess for the presence or absence of spontaneous venous pulsations (SVPs). SVPs are only present when ICP is normal. Visualization of SVPs can reassure the provider that ICP is not critically elevated.[8] See Appendix C for additional information on the rapid assessment of SVPs.
- Consider early C-spine immobilization. The incidence of concomitant brain and spinal cord injury in trauma ranges from 25% to 60%, with motor vehicle crashes and falls having the highest incidence of co-occurence.[9] Ensure the cervical collar does not compress the jugular veins in the neck, because that could worsen ICP.
- The neurologic examination is essential to identify deterioration in a TBI patient. Treat for elevated ICP for any deterioration in neurologic examination findings.
- Pain medication and sedation are usually required for TBI patients; however, these medications also make it difficult to follow the neurologic examination.
- Obtain a telemedicine consultation if possible. If in doubt, treat for elevated ICP according to ICP management outlined in the next section.
- Close control of $EtCO_2$ is critical for severe TBI patients. Plan and ensure the capability to monitor $EtCO_2$ is available whenever advanced airway is placed. Goal $EtCO_2$ is 35–40mmHg.

Cushing's triad (i.e., increased SBP and/or widening pulse pressure, bradycardia, and irregular respirations) is a physiologic response that can occur with elevated ICPs, resulting in medullary compression. It is a late finding of severe brain injury with brainstem herniation. Cushing's triad should be viewed as a sign of cerebral herniation and addressed immediately when recognized (see ICP Management).

MANAGEMENT

HEMODYNAMIC CONTROL

Goal: Maintain SBP >110mmHg. In polytrauma patients with ongoing bleeding, aggressively control hemorrhage using all means available and restore circulating blood volume by using blood products.
***Note**: An SBP >90mmHg has traditionally been targeted in TBI patients, though recent literature has suggested better outcomes may occur when SBP is maintained above 110mmHg in TBI patients*.[10,11]

- **Minimum**: Stop all external bleeding. Manage internal bleeding to the extent possible with available resources. Administer tranexamic acid (TXA) per TCCC guidelines. Avoid medications that may lower the blood pressure (e.g., narcotics).
- **Better**: If there is evidence of bleeding and no blood products are available, administer 1L 0.9% sodium chloride (NaCl). Target is an SBP >110mmHg.
- **Best**: If there is evidence of bleeding, transfuse whole blood or, if not available, transfuse blood products. Greater emphasis on the use of Low Titer O Whole Blood is the optimal strategy. Target is an SBP >110mmHg.

Hemodynamic Control Notes

- Do not neglect scalp bleeding. This can become a significant source of blood loss. Scalp lacerations should be sutured or stapled as soon as possible.
- Take caution if an underlying skull fracture is present or if there is obvious penetrating trauma. DO NOT tightly pack or irrigate an open head wound. Suture or staple the skin closed, if bleeding. A pressure dressing may be placed if needed to control bleeding.
- Hypotension is usually not caused by TBI except as a late finding due to herniation.[12] Always look for other causes of hypotension, such as ongoing bleeding or tension pneumothorax.
- Urine output (UOP) provides an important assessment of blood supply to the organs. Monitoring continuously by a Foley catheter is ideal. If a Foley catheter is not available, monitor by a graduated cylinder. Goal UOP in a polytrauma patient is 30–50mL/h.[13]
- The role of TXA in TBI patients is currently under investigation in the CRASH-3 trial. Limited data suggest TXA limits ICH expansion and may improve outcomes in TBI patients.[14] Until more definitive data are available, TXA can be used in TBI patients.
- Colloids (e.g., albumin) have demonstrated a trend toward worsening outcomes in brain-injured patients.[15] Hetastarches are associated with coagulopathy and increased risk of kidney injury in trauma patients.
- Avoid colloids and hetastarches in TBI patients; however, they can be used if no alternative is available.

- Avoid hypotonic fluids (including lactated Ringer's) whenever possible; they can make brain swelling worse.

Most trauma patients with moderate or severe TBI will have other traumatic injuries. A careful search for bleeding should be performed in any hypotensive trauma patient.

Brain injury with associated hemorrhagic shock is a complicated scenario with a high risk of death. Balancing hemorrhage control (which is easier with lower blood pressure) with maintaining cerebral perfusion pressure (which requires higher blood pressure) should be guided with expert teleconsultation (i.e. critical care, neurocritical care, neurosurgical) whenever possible.

AIRWAY, OXYGENATION/VENTILATION MANAGEMENT

Goal: Manually maintain or secure the patient's airway and avoid hypoxia, hypocapnia, or hypercapnia to reduce the risk of secondary brain injury. If GCS score is ≤8 or there is facial trauma with compromised airway, a definitive airway is most likely needed. The provider should place the type of airway (i.e. cricothyroidotomy or endotracheal tube [ETT]) that they have the most confidence in placing, based on their training and practice.

- **Minimum**: Nasopharyngeal airway and bag-valve-mask with PEEP valve as needed. Use supplemental oxygen, if available. Maintain SpO_2 >90%.
- **Better**: Perform a cricothyroidotomy/ETT placement or place a supraglottic airway (e.g., laryngeal mask airway [LMA], King laryngeal tube [LT]) followed by continuous sedation and airway maintenance, supplemental oxygen via oxygen concentrator, and portable ventilator to maintain an SpO_2 >95% and $EtCO_2$ of 35–40mmHg.
- **Best**: Cricothyroidotomy or ETT followed by continuous sedation and airway maintenance, supplemental oxygen, portable ventilator. Targets: SpO_2 >95% and $EtCO_2$ 35–40mmHg. Check arterial blood gas results and correlate with $EtCO_2$ within 30 minutes of intubation if laboratory capability is available. A positive end-expiratory pressure (PEEP) of 5cmH_2O should be used routinely. PEEP can be safely increased up to 15cmH_2O if needed to improve SpO_2, but be alert for problems caused by increased intrathoracic pressure (e.g., lower blood pressure or increased ICP).[16]

Airway Management Notes

- Patients with a GCS score ≤8 should undergo placement of an advanced airway (i.e. cricothyroidotomy or ETT) unless arrival to a higher level of care will occur in a timely manner or the airway can be manually maintained. The risk versus benefit of advanced airway placement should be carefully considered and discussed by telemedicine consultation whenever possible.
- Airway interventions may cause transient hypoxia during the procedure. Every effort should be made to optimize airway placement on the first attempt by preoxygenating with supplemental O_2, selecting the most experienced provider available, and using the technique most familiar to the provider.
- Patients typically require less sedation after cricothyroidotomy than after ETT placement. This may help conserve resources if medications are limited.
- Monitor $EtCO_2$ and adjust ventilations to achieve the target range. Avoid hyperventilation ($EtCO_2$ <35mmHg) except in extreme cases where imminent herniation is suspected, because hyperventilation worsens cerebral ischemia. Also avoid hypoventilation ($EtCO_2$ >45mmHg) that will increase ICP.

- Gastric decompression with a nasogastric tube (NGT) or oral gastric tube (OGT) will decrease the risk of aspiration in unconscious patients. If patients required bag-masking, they may have a distended stomach, which, in some patients, contributes to bradycardia. NGT and OGT cannot be placed with a supraglottic airway.

ICP MANAGEMENT

Goal: Suspect high ICP in any head injury patient with GCS score ≤8 OR declining findings on neurologic examination (unless explained by sedation, hypotension, hypoxia, hypercarbia, high fever). Minimize factors that contribute to elevated ICP, such as pain, anxiety, and fever. Rapidly recognize and manage elevated ICP, and maintain an adequate cerebral perfusion pressure.

- **Minimum**: Use general measures to reduce ICP.
  - Elevate head of bed (HOB) 30°–60°.
  - Maintain neck in midline position.
  - Maintain arterial blood oxygen saturation (SpO_2) >90% (or >95% if receiving ventilatory support).
  - Maintain $EtCO_2$ between 35mmHg and 40mm Hg.
  - Maintain core temperature between 96°F and 99.5°F.
  - Maintain SBP >100mmHg, ideally at >110mmHg.
  - Prevent or rapidly manage seizure activity.
  - If concerned for impending herniation (e.g., unresponsive patient with unilateral dilated pupil, presence of Cushing's triad), hyperventilate the patient for no more than 20 minutes to an $EtCO_2$ target of 30mmHg.[17] Seek expert consultation immediately.

The optimum duration of hyperventilation and frequency that can be repeated are not known. If performed, assess response (i.e. pupils, GCS score, and so forth). If patient responds, consider performing again if needed, guided by expert teleconsultation, if possible

- **Better**: Even unconscious patients may experience pain and anxiety, manifested by hypertension (i.e., SBP >160mmHg) and/or agitation. Anxiety and agitation can increase ICP. In addition to all minimum measures, ensure adequate sedation and analgesia by targeting a Richmond Agitation and Sedation Score of −1 to −2. Refer to Joint Trauma System CPG on PFC Analgesia and Sedation.[18]
  - Ketamine 20mg IV/IO
  - Hydromorphone 0.5–2mg IV/IO
  - Fentanyl 25–50µg IV/IO

  In addition to analgesics, consider administration of a rapid-onset, short-duration anxiolytic. Midazolam 1–2mg IV/IO as needed for agitation or anxiety.

- **Best**: In addition to all minimum and better measures, administer osmotic therapy via peripheral intravenous (IV) or intraosseous (IO) access:
  - Hypertonic saline (HTS): 3% NaCl 250mL bolus over 20 minutes; repeat every 3 hours as needed when concerned for elevated ICP.

- Mannitol can be used if there is no sign of bleeding and the SBP is >110mmHg. Mannitol 1g/kg IV/IO over 20 minutes. Repeat at 0.5g/kg IV/IO every 3 hours as needed when concerned for elevated ICP.

Seek additional medical direction as soon as possible and evacuate to neurosurgical care at the earliest opportunity.

ICP Management Notes

- ICP cannot be directly measured without advanced intracranial monitoring devices. Therefore, vigilant clinical observation and the use of noninvasive ICP assessment modalities are critical to monitoring TBI patients until neurosurgical placement of neuromonitoring devices can occur.
- HTS bolus lowers ICP and has a duration of action of approximately 3 hours.[19,20]
- Mannitol, although effective, has several potentially adverse complications. It is a diuretic and might lower the blood pressure. Also, after repeated use, it can cross a damaged blood–brain barrier and potentially worsen ICP.[20] For these reasons, HTS is preferred to mannitol in TBI and polytrauma patients.
- Some institutions have reported ICP-lowering benefits from vertical positioning of patients, particularly when high intraabdominal or intrathoracic pressure is suspected. Lower intraabdominal and intrathoracic pressures may facilitate venous drainage from the intracranial compartment. If safe to do so, this can be attempted when other measures have failed.[21]

Always treat hypotension before treating elevated ICP. Cerebral blood flow is more affected by a decrease in blood pressure than an increase in ICP.

Cerebral perfusion pressure (CPP) = mean arterial pressure (MAP; mmHg) − ICP (mmHg)

Hyperventilation reduces CO_2 and rapidly lowers ICP by causing cerebral vasoconstriction and decreasing the overall cerebral blood volume. However, hyperventilation also damages the brain by causing ischemia and should only be performed for brief periods. Avoid hyperventilation unless all other interventions have been ineffective.[22]

Although there are invasive interventions to help assess and treat elevated ICP, evacuate hematomas, and so forth, such as decompressive craniectomy, extraventricular drains, intracranial bolt monitors, and burr holes, such procedures are not recommended unless the PFC provider has training and experience in performing these procedures and is directed by expert teleconsultation.

INFECTION CONTROL

Goal: Dress all wounds to prevent further exposure to environmental pathogens and administer antibiotic prophylaxis to all patients with penetrating TBI.

- **Minimum**: Dress all wounds to prevent further introduction of infectious materials. Optimize wound and patient hygiene to the extent possible given the environmental and situational conditions.
  - For penetrating head wounds, apply superficial dressings and seal the dressing to the extent possible.

- Bleeding head injuries must be sutured or stapled to control bleeding.
- DO NOT introduce any material into the wound cavity.
- DO NOT attempt to flush the wound.
- Antibiotics are not necessary in TBI without open or penetrating trauma.

- **Better**: Antibiotics should be used for open or penetrating TBI.
  - Ertapenem 1g IV/IO every 24 hours and moxifloxacin 400mg PO every 24 hours for 5 days.

Ertapenam and moxifloxacin may increase the risk of seizure and ertapenam may not penetrate an intact blood-brain barrier. This combination, while commonly available, should only be used in TBI patients when the antibiotics with proven CNS penetration are not available.

- **Best**: Administer CNS-penetrating antibiotics for open or penetrating TBI.
  - Ceftriaxone 2 gm IV/IO every 24 hours or cefazolin 2g IV/IO every 8 hours for 5 days. .
  - Add metronidazole 500mg IV/IO every 8 hours for 5 days for wounds that are grossly contaminated with organic debris (e.g., dirt, debris, clothing).[17]

- **Infection Control Notes**
  - Moxifloxacin may be replaced with levofloxacin 750 mg PO daily to provide better coverage of bacteria found in wet terrain/ jungle environment.
  - If recommended antibiotics are not available or significant drug allergies are present, obtain teleconsultation to discuss alternative medications. Additional detailed recommendations may found in Forgione et al.[23]

SEIZURE PROPHYLAXIS AND MANAGEMENT

Goal: Rapidly identify and manage seizure activity in TBI patients.

- **Minimum**: For witnessed convulsive seizure activity, place the patient on his/her side and clear the area of any potentially harmful objects. Suction the mouth if possible, but DO NOT attempt to place anything inside a seizing patient's mouth. Treat any witnessed or suspected seizures with a rapid-acting benzodiazepine.
  - Midazolam 5mg IV/IO/IM every 5 minutes until seizure stops.
  - An alternate benzodiazepine can be used if available (diazepam 5mg IV every 5 minutes until seizure stops; lorazepam 4mg IV every 5 minutes until seizure stops).

- **Best**: For witnessed or suspected seizures, administer a rapidly acting benzodiazepine (midazolam 5mg IV/IO/intramuscularly [IM]) plus a maintenance antiepilepsy drug. Broad-spectrum IV agents such as levetiracetam (Keppra; UCB Pharma, http://www.ucb.com/) are preferred.
  - Maintenance antiepilepsy-drug dosing: Levetiracetam: 2000mg IV/IO loading dose over 15 minutes followed by maintenance dosing of 500mg IV/IO every 12 hours.
  - Alternate maintenance antiepilepsy drugs:

- Phenytoin (loading dose: 1.5g IV over 1 hour, then 100mg PO/IV/IO every 8 hours)
- Phenobarbital (loading dose: 1.5g IV/IO over 1 hour, then 100mg PO/IV/IO daily). Be ready to support ventilation if phenobarbital is used.

Seizure Notes

- Not all seizures are easy to see. At times, the findings may be obvious with generalized convulsions, or they may be subtle (e.g., persistent twitching of facial muscles, fingers).
- Risk factors for seizures after TBI include: GCS score <10, skull fractures, penetrating injuries, prolonged length of coma (>24 hours).[24]
- Non-convulsive seizures (NCSs) should be considered in any TBI patient with a GCS score ≤8 and who does not improve with appropriate resuscitation and/or ICP management. NCSs may persist after convulsive seizures are stopped and may be associated with higher morbidity and mortality.[25] The most common signs of patients with NCS are coma, delirium, agitation, aphasia (impairment of language affecting production and/or comprehension of speech, reading, and/or writing) and/or "blank staring."
- Prompt initiation of seizure prophylaxis reduces early seizures after TBI.[26] In PFC settings, where possible, an anti-epilepsy drug should be used early after injury to help prevent seizure.
- Midazolam has a high rate of seizure control and works rapidly to terminate seizure activity.[27] Midazolam is preferred because it is a short-acting medication (elimination time: 2–4 hours) and will allow for more regular and comprehensive neurologic examinations. It can be given IM in patients who do not yet have IV/IO access.
- If not already placed, strong consideration should be given to placing an advanced airway (cricothyroidotomy or ETT) in any TBI patient who experiences seizures (place airway after seizures are controlled).

FEVER CONTROL

Goal: Maintain core temperature between 96°F and 99.5°F. Treat fever aggressively in TBI patients with a combination of medication, cold fluid boluses, and surface cooling techniques.

- **Minimum**: Ensure patient has been removed from heat or sun. Remove clothes to allow evaporative cooling, Use surface-cooling measures (e.g., evaporative heat loss by misting and fan cooling) to reduce core body temperature.
- **Better**: Apply cold packs to axillary regions, posterior cervical region, and the groin.
- **Best**: Acetaminophen 650mg every 4 hours orally (PO) or rectally as needed for rectal temperatures >99.5°F. Additionally, cold saline IV fluid bolus can be used for refractory fever, if available.

Fever Notes

- Fever will increase cerebral metabolism and may increase ICP.
- Although targeted temperature management (previously referred to as therapeutic hypothermia) is used to reduce ICP in a critical care setting, hypothermia is part of the "lethal triad" in trauma patients, along with coagulopathy and acidosis. Targeted temperature management strategies beyond what is outlined in TCCC should NOT be attempted in the field or Role 1 setting.

- Hypothermia prevention and management kits should continue to be used in all trauma patients. In TBI patients, however, warming measures should be avoided when the core body temperature is above the target range.

Avoid non-steroidal anti-inflammatory drugs (NSAIDs), such as ibuprofen, naproxen, ketorolac. Although these agents can effectively lower temperature, their antiplatelet effect may increase bleeding in TBI if intracranial hemorrhage is present (e.g., epidural hematomas, subdural hematomas).

SODIUM MANAGEMENT

Goal: Avoid hyponatremia, which can worsen brain swelling. The target serum sodium level in patients with severe TBI is slightly above normal, between 145mmol/L and 160mmol/L.

- **Minimum**: Avoid the administration of any free water or hypotonic fluids that will lower serum sodium levels.
- **Best**: Monitor serum sodium level via blood sampling. In a stable patient, check sodium level every 6 hours. In an unstable patient, or in a patient receiving HTS, check sodium level every 3 hours. Adjust fluids as needed to meet the sodium goals.

Sodium Management Notes

- Several conditions can develop rapidly in brain-injured patients that can lower serum sodium levels (e.g., cerebral salt wasting, syndrome of inappropriate antidiuretic hormone secretion) or raise serum sodium levels (e.g., diabetes insipidus). Sodium levels, fluid intake, and urine output should be monitored closely.
- If laboratory testing for serum sodium level is not available, then, as a reference, 250mL of 3% saline can be expected to raise the serum sodium level of an 80kg patient approximately 2–3mmol/L. Assuming a normal serum level of 140mmol/L before starting HTS therapy, it would take six 250mL bags of 3% HTS to raise the serum sodium to concerning levels (i.e. >160mmol/L). This is without factoring in the regulation of serum sodium by the kidneys. If patient is urinating, it will be difficult to raise serum sodium above 160mmol/L with 3% HTS. If patient is not urinating, more caution should be used because sodium levels can build up more quickly.

Obtain telemedicine consultation, preferably from a critical care or neurocritical care expert, before giving more than two 250mL boluses of 3% NaCl HTS.

BLOOD GLUCOSE CONTROL

Goal: Avoid both hypolgycemia and hyperglycemia. Target a blood glucose level of 180mg/dL via handheld glucometer.

- **Minimum**: Monitor for clinical signs and symptoms of hypoglycemia (e.g., sweating, confusion, tremor, generalized weakness, generalized lethargy). If patient is hungry and able to safely swallow, allow the patient to eat to avoid hypoglycemia. Avoid the administration of any substances that are excessively high in sugar or carbohydrate content to prevent hyperglycemia.
- **Best**: Check blood glucose level every 6 hours. If glucose level is <100mg/dL, give 20g of oral glucose (5 teaspoons of sugar or 4 teaspoons of honey) PO or by NG tube. Or administer 25g (50mL) dextrose 50% in water (D50) solution IV/IO. Recheck blood glucose in 1 hour, then continue to check every 6 hours.

Blood Glucose Control Notes

- Hypoglycemia is more harmful to the brain than hyperglycemia.
- Hyperglycemia may occur in TBI as an acute stress response or as a result of brain-induced catecholamine release. Early hyperglycemia (i.e., >180mg/dL) has been associated with poor neurologic outcome in severe TBI.[28]
- The treatment of hyperglycemia requires insulin. If the appropriate medications, laboratory capability, and expertise are available, hyperglycemia may be treated; however, the treatment of hyperglycemia is not covered in this CPG.

TRANSPORTATION CONSIDERATIONS

Goal: Safely prepare TBI patients for ground and/or air transportation to higher levels of care.

- **Minimum**: Dose sedative/analgesic medications, osmotic agent, and/or benzodiazepine before any significant ground or air transportation, as resources permit.

  Neuromuscular blocking agents will mask seizures and clinical examination changes; therefore, the risk versus benefit of use during transport must be considered.

- **Best**: Ensure transport assets are aware of the patient's brain injury in advance so appropriate accommodations and/or alterations to the travel plan can be made.
  - Most patients are transported in a supine position. Every effort should be made to transport TBI patients with the HOB elevated to at least 30°.
  - For fixed-wing transport, TBI patients should be loaded with their head toward the front of the aircraft to minimize G-forces transmitted to the brain.
  - Air transport of TBI patients requires additional considerations. For air movements that involve altitudes >8,000 ft, TBI patients are at risk for additional complications that may worsen brain injury, such as hypobaric hypoxia and high-altitude cerebral edema.[29] Preplanning with air assets is highly recommended.
- Recommended Packing List. See Appendix D.
- Management of Traumatic Brain Injury Summary Table. See Appendix E.

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

1. All patients with a diagnosis of traumatic brain injury and an initial GCS of 3-8.
2. All patients who receive a cranial procedure (ICP monitor, craniectomy, craniotomy).

INTENT

1. All patients in population of interest avoid hypotension and hypoxia: SBP never < 100 mmHg, MAP never < 60, SaO2 never < 93%.

2. All patients in population of interest have PaCO2 monitored at every role of care.
3. All patients in population of interest have a head CT performed within 4 hours of injury.
4. All patients with a ventriculostomy have hourly documentation of ICP/CPP and ventriculostomy output.
5. Patients in population of interest unable to be monitored clinically (e.g., unable to hold sedation for Q1 hour neuro exam) have an ICP monitor or ventriculostomy placed prior to transport out of theater.

METRICS

1. Number and percentage of patients in the population of interest with lowest SBP<100 within first 3 days after injury.
2. Number and percentage of patients in the population of interest with MAP<60 within first 3 days after injury.
3. Number and percentage of patients in the population of interest with SaO2<93% within first 3 days after injury.
4. Number and percentage of patients in population of interest who have PaCO2 documented at every role of care (POI, POI MEDEVAC, ROLE 2-4, interfacility MEDEVAC).
5. Number and percentage of patients in the population of interest who maintain PaCO2=35-40
6. Number and percentage of patients who had a head CT performed within 4 hours of injury.
7. Number and percentage of patients with a ventriculostomy who had hourly documentation of ICP/CPP and ventriculostomy output.
8. Number and percentage of patients in the population of interest unable to be monitored clinically (eg. unable to hold sedation for Q1 hour neuro exam) who have an ICP monitor or ventriculostomy placed prior to transport out of theater.

DATA SOURCE

- Patient Record and the ASIA or Combat Neuro Exam worksheet
- Department of Defense Trauma Registry (DoDTR)

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the Joint Trauma System (JTS) Chief and the PI Branch.

APPENDIX A: NEUROLOGICAL EXAMINATION

I. MENTAL STATUS

Level of Consciousness: Note whether the patient is:

- Alert/responsive
- Not alert but arouses to verbal stimulation
- Not alert but responds to painful stimulation
- Unresponsive

Orientation: Assess the patient's ability to provide:

- Name
- Current location
- Current date
- Current situation (e.g., ask the patient what happened to him/her)

Language: Note the fluency and appropriateness of the patient's response to questions. Note patient's ability to follow commands when assessing other functions (e.g., smiling, grip strength, wiggling toes). Ask the patient to name a simple object (e.g., thumb, glove, watch).

Speech: Observe for evidence of slurred speech.

II. CRANIAL NERVES

All patients:

- Assess the pupillary response to light.
- Assess position of the eyes and note any movements (e.g., midline, gaze deviated left or right, nystagmus, eyes move together versus uncoupled movements).

Noncomatose patient:

- Test sensation to light touch on both sides of the face.
- Ask patient to smile and raise eyebrows, and observe for symmetry.
- Ask the patient to say "Ahhh" and directly observe for symmetric palatal elevation.

Comatose patient:

- Check corneal reflexes; stimulation should trigger eyelid closure.
- Observe for facial grimacing with painful stimuli.
- Note symmetry and strength.
- Directly stimulate the back of the throat and look for a gag, tearing, and/or cough.

III. MOTOR

Tone: Note whether resting tone is increased (i.e. spastic or rigid), normal, or decreased (flaccid).

Strength: Observe for spontaneous movement of extremities and note any asymmetry of movement (i.e. patient moves left side more than right side). Lift arms and legs, and note whether the limbs fall immediately, drift, or can be maintained against gravity. Push and pull against the upper and lower extremities and note any resistance given. Note any differences in resistance provided between the left and right sides.

(NOTE: it is often difficult to perform formal strength testing in TBI patients. Unless the patient is awake and cooperative, reliable strength testing is difficult.)

Involuntary movements: Note any involuntary movements (e.g., twitching, tremor, myoclonus) involving the face, arms, legs, or trunk.

IV. SENSORY

If patient is not responsive to voice, test central pain and peripheral pain.

Central pain: Apply a sternal rub or supraorbital pressure, and note the response (e.g., extensor posturing, flexor posturing, localization).

Peripheral pain: Apply nail bed pressure or take muscle between the fingers, compress, and rotate the wrist (do not pinch the skin). Muscle in the axillary region and inner thigh is recommended. Apply similar stimulus to all four limbs and note the response (e.g., extensor posturing, flexor posturing, withdrawal, localization).

NOTE: In an awake and cooperative patient, testing light touch is recommended. It is unnecessary to apply painful stimuli to an awake and cooperative patient.

V. GAIT

If the patient is able to walk, observe his/her casual gait and note any instability, drift, sway, and so forth.

APPENDIX B: ULTRASONIC ASSESSMENT OF OPTIC NERVE SHEATH DIAMETER

If a patient is unconscious (i.e. does not follow commands or open eyes spontaneously), they may have elevated ICP. There is no reliable test for elevated ICP available outside of a hospital; however, optic nerve sheath diameter (ONSD) measurement is a rapid, safe, and easy-to-perform ultrasonographic assessment that may help identify elevated ICP when more definitive monitoring devices are not available.

- The optic nerve sheath directly communicates with the intracranial subarachnoid space. Increased ICP, therefore, displaces cerebrospinal fluid along this pathway. Normal ONSD is 4.1–5.9mm.[30]
- A 10–5-MHz linear ultrasound probe can be used to obtain ONSDs. ONSD is measured from one side of the optic nerve sheath to the other at a distance of 3mm behind the eye immediately below the sclera.[31]
- In general, ONSDs >5.2mm should raise concern for clinically significant elevations in ICP in unconscious TBI patients.[5,32] The ONSD can vary significantly in normal individuals, so one single measurement may not be helpful; however, repeated measurements that detect gradual increases in ONSD over time may be more useful than a single measurement.
- ONSD changes rapidly when the ICP changes, so it can be measured frequently.[33] If ONSD is used, it is best to check hourly along with the neurologic examination.

TECHNIQUE

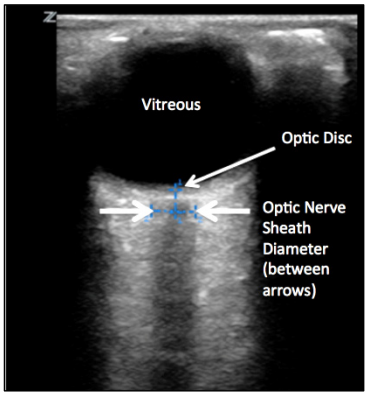
1. Check to make sure there is no eye injury. A penetrating injury to the eyeball is an absolute contraindication to ultrasound because it puts pressure on the eye.
2. Ensure the head and neck are in a midline position. Gentle sedation and/or analgesia may be necessary to obtain accurate measurements.
3. Ensure the eyelids are closed.
4. If available, place a thin, transparent film (e.g., Tegaderm; 3M, http://www.3m.com) over the closed eyelids.
5. Apply a small amount of ultrasound gel to closed eyelid.
6. Place the 10(–5)MHz linear probe over the eyelid. The probe should be applied in a horizontal orientation (Figure 1) with as little pressure as possible applied to the globe.
7. Manipulate the probe until the nerve and nerve sheath are visible at the bottom of screen. An example of a proper ultrasonagraphic image of the optic nerve sheath can be seen in Figure 2.
8. Once the optic nerve sheath is visualized, freeze the image on the screen.
9. Using the device's measuring tool, measure 3mm back from the optic disc and then obtain a second measurement perpendicular to the first. The second measurement should cover the horizontal width of the optic nerve sheath (Figure 2). An abnormal ONSD is shown in Figure 3.
10. Repeat the previous sequence in the opposite eye. Annotate both ONSDs on the PFC Casualty Card.
11. ONSDs should be obtained, when possible, at regular intervals to help assess changes in ICP, particularly when the neurologic examination is poor and/or unreliable (i.e. with sedation). Serial measurements with progressive diameter enlargement and/or asymmetry in ONSDs should be considered indicative of worsening intracranial hypertension.

CAUTION: ONSD measurements are contraindicated in eye injuries. NEVER apply pressure to an injured eye.

Figure 1. *Appropriate placement of the linear probe.*

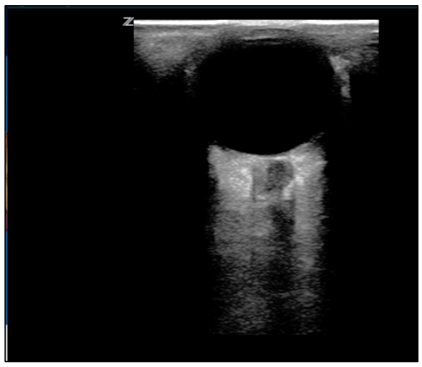
Ultrasound gel is placed over a closed eyelid and the probe placed horizontally over the eyelid, applying as little pressure to the globe as possible. If available, Tegaderm or other thin covering (e.g., Latex glove) should be placed over a closed eyelid for further protection.

Figure 2 *An ultrasonographic view of a normal eye and optic nerve sheath.*



To measure ONSD, apply the ultrasound measuring device to the optic disc and measure back 3mm along the length of the optic nerve. A second, perpendicular measurement is obtained at the previously measured point that spans the horizontal width of the optic nerve sheath. In this image, ONSD was determined to be 5.1mm, a normal value.

Figure 3*. Ultrasound image of the right optic nerve sheath of a 61-year-old man with a traumatic subdural hematoma.*



The optic nerve sheath measured 6.8mm in diameter. Elevated ICP was subsequently confirmed (26mmHg) after the placement of an ICP bolt monitor.

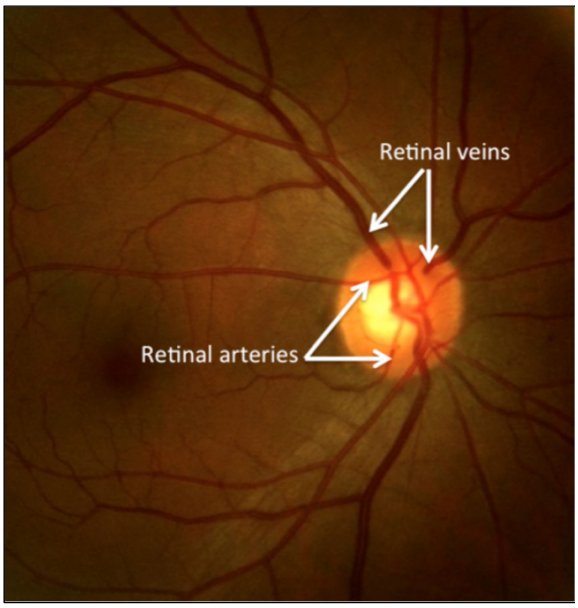
APPENDIX C: SPONTANEOUS VENOUS PULSATIONS

- Spontaneous venous pulsations (SVPs) are subtle, rhythmic variations in retinal vein caliber on the optic disc and have an association with ICP.
- It is difficult to see SVPs without advanced equipment; however, if a handheld ophthalmoscope is available, it is worth an attempt to visualize the retinal veins.
- Don't worry if you cannot see SVPs; this may actually be normal. However, if you do see them, it is very reassuring that ICP is normal.[10]
- If SVPs are initially present and can no longer be seen on subsequent examinations, the provider should be concerned for increasing ICP.

TECHNIQUE

1. Gently lift the eyelid until the pupil is in view.
2. Using a handheld ophthalmoscope, the provider should maneuver himself or herself to a position where the optic disc can be visualized.
3. Identify the retinal veins as they emerge from the optic disc. Retinal veins are typically slightly larger and darker than retinal arteries. Figure 1 demonstrates the typical appearance of the retina.
4. Observe the retinal veins for pulsations. Note the presence or absence of spontaneous venous pulsations
5. Repeat the step 1–4 sequence in the contralateral eye.

Figure 1. *Typical appearance of a healthy retina.*



The retinal vessels can be seen emerging from the optic disc. Retinal veins can be identified by their slightly larger, thicker size and darker color. Retinal arteries are small, thin, and lighter in color than retinal veins.

APPENDIX D: RECOMMENDED PACKING LIST

Assumptions: One patient with a moderate to severe traumatic brain injury. To calculate the amount of fluid or medication you would need for a single TBI patient, use your worst case, longest possible evacuation extrapolated from your mission planning. For example, if you think you might have a 36-hour evacuation, you might need 3,500mg levetiracetam (a 2,000mg loading dose and 500mg every 12 hours)

MINIMUM

- **Equipment**: vital-sign trending chart, BP cuff, stethoscope, wrist watch, pulse oximeter, capnometer, cricothyroidotomy kit, bag-valve-mask with PEEP valve, nasopharyngeal airway, disposable thermometer, Nalgene bottle to measure urine
- Medications/Fluids: ketamine, midazolam, lorazepam, acetaminophen, ceftriaxone, 3% hypertonic saline

BETTER

- **Equipment**: portable vital sign monitor, capnometer, cricothyroidotomy kit and/or ETT plus laryngoscope/glidescope and/or laryngeal mask airway, cold/ice packs, graduated cylinder to measure urine, oxygen concentrator
- Medications/Fluids: ketamine, IV hydromorphone, IV fentanyl, midazolam

BEST

- **Equipment**: portable monitor providing continuous vital-signs display with capnography, cricothyroidotomy kit, and/or ETT plus laryngoscope/glidescope, portable point-of care-testing device such as an iStat (Abbott Point of Care; https://www.pointofcare.abbott) or Epoch (Alere, http://www.alere.com) for arterial blood gas samples, and electrolyte monitoring, blood glucose monitor, Foley catheter kit, and supplemental oxygen or oxygen concentrator
- Medications/Fluids: Fresh whole blood drawing supplies or stored blood products, 3% hypertonic saline, mannitol, ceftriaxone, metronidazole, levetiracetam or phenytoin, acetaminophen, dextrose 50% in water

OTHER PACKING LIST CONSIDERATIONS

- **Equipment**: Portable ultrasound, nasogastric tube, red- (or red/yellow-speckled) top test tubes to test for electrolytes if a host-nation laboratory is available
- Medications/Fluids: TXA

APPENDIX E: MANAGEMENT OF TRAUMATIC BRAIN INJURY SUMMARY TABLE

Management of Traumatic Brain Injury Summary			
GOAL	**MINIMUM**	**BETTER**	**BEST**
Neurological Assessment			
Goal: Rapidly identify TBI and associated injuries; assess TBI severity.	Consider: If patient is unconscious, measure a baseline optic nerve sheath diameter with ultrasound using a 10(–5)MHz linear probe.	Secondary survey: Evaluate for TBI red flags. Perform detailed neurologic examination.	Primary survey: Perform rapid trauma survey to assess all injuries. Determine and record Glasgow Coma Score. Assess pupils and motor function in all four extremities. Recognize Cushing's triad.
ONSD should not be attempted on any patient with an open globe injury to the eye. Cushing's triad: increased SBP/widened pulse pressure, bradycardia, irregular breathing (typically rapid/shallow)			
Monitoring			
Prevent secondary brain injury, maintain adequate oxygenation and ventilation, avoid hypotension, detect elevated ICP.	Blood pressure cuff, stethoscope, pulse oximeter, method to monitor urine output. If advanced airway is in place, monitor $EtCO_2$ with capnometer. Check pupils and GCS hourly or as often as possible.		Portable monitor with continuous vital-signs display, Foley catheter to monitor urine output. If advanced airway in place, monitor end-tidal CO_2 ($EtCO_2$) with capnography. Check pupils and GCS hourly.
Neurologic examination and vital-sign trends are essential to identifying a deteriorating patient with TBI. Monitoring $EtCO_2$ is critical for severe TBI patients. Bring the correct equipment whenever possible.			
Management Hemodynamic Control			
Maintain systolic pressure >110mmHg	Stop all external bleeding. Manage internal bleeding to the extent possible with available resources. Administer TXA per TCCC guidelines. Avoid medications that may lower the blood pressure.	If there is evidence of bleeding and no blood products are available, 0.9% sodium chloride 1L. Target SBP: >110mmHg	If evidence of bleeding, transfuse whole blood or, if not available, transfuse blood products per TCCC guidelines. Target SBP: >110mmHg
Brain injury in the presence of hemorrhagic shock requires balancing hemorrhage control with cerebral perfusion. Telemedicine consultation is strongly encouraged. Do not neglect scalp bleeding. Take care to inspect for skull fractures. DO NOT tightly pack an open head wound. Hypotonic fluids (to include lactated Ringer's) should be avoided whenever possible because they can worsen cerebral edema.			
Management: Airway, Oxygenation/Ventilation			
Maintain or secure airway. If GCS score ≤8 or there is facial trauma or other airway compromise, consider definitive airway placement.	Nasopharyngeal airway and bag-valve-mask with PEEP. Supplemental oxygen, if available. Maintain SpO_2 >90%.	Perform cricothyroidotomy/ETT or place supraglottic airway followed by continuous sedation, supplemental O_2, portable ventilator. Target SpO_2: >95%, $EtCO_2$: 35–40mmHg.	Perform cricothyroidotomy/ETT followed by continuous sedation, supplemental O_2, portable ventilator. Target SpO_2 >95%, $EtCO_2$ 35–40. Check arterial blood gas values. PEEP: 5cmH_2O (increase up to 15cmH_2O if needed).
Avoid hyperventilation except in extreme cases where imminent cerebral herniation is suspected.			
Management ICP			
Suspect high ICP in any head injury patient with GCS score ≤8 or declining findings on neurologic examination. Minimize factors that could contribute to elevated ICP, such as pain, anxiety, and fever.	• Elevate HOB 30–45° • Neck midline, loosen collar • SBP >110mmHg (or at least > 100mmHg) • SpO_2 >90% or 95% on ventilator • $EtCO_2$ 35–40mmHg • Core temp 96–99.5°F • Prevent/treat seizure • Last choice if sign of herniation: hyperventilate to $EtCO_2$ 30mmHg × 20 minutes.	In addition to minimum steps, ensure adequate sedation and analgesia. If SBP >160mmHg or agitated: • Ketamine 20mg IV/IO • Hydromorphone 0.5–2mg IV/IO • Fentanyl 25–50µg IV/IO • Midazolam 1–2mg IV/IO	In addition to minimum and better steps, give osmotic therapy IV/IO: • HTS 3% 250mL over 20 minutes. Repeat every 3 hours if needed. • Mannitol (If no bleeding and SBP >110mmHg) 1g/kg IV/IO over 20 minutes, repeat 0.5g/kg every 3 hours, if needed.
Telemedicine consultation early and often in the patient with elevated ICP.			
Management: Infection Control			
Dress all wounds and administer antibiotic prophylaxis for penetrating brain injuries and open wounds.	Dress all wounds to prevent further introduction of infection. Optimize wound care and patient hygiene to extent possible.	Ertapenem 1g IV/IO every 24 hours and moxifloxacin 400mg PO every 24 hours for 5 days.	Use an antibiotic with strong CNS penetration. • Ceftriaxone 2 gm IV/IO every 24 hours or cefazolin 2g IV/IO every 8 hours for 5 days • Add metronidazole 500mg IV/IO every 8 hours if wounds contaminated with organic debris.
Moxifloxacin may be replaced with levofloxacin 750 mg PO daily to provide better coverage of bacteria found in wet terrain/ jungle environment. Ertapenam and moxifloxacin may increase the risk of seizure and ertapenam may not penetrate an intact blood-brain barrier. If recommended antibiotics are not available or significant drug allergies are present, obtain teleconsultation to discuss alternative medications.			

Management of Traumatic Brain Injury Summary			
GOAL	**MINIMUM**	**BETTER**	**BEST**
Management: Seizures			
Rapidly identify and manage seizures.	For a witnessed or suspected seizure, ensure safety and airway is clear. Treat with rapid-acting benzodiazepine: · Midazolam 5mg IV/IO/IM every 5 minutes until seizure stops		Levetiracetam 2,000mg IV/IO loading dose over 15 minutes + 500mg every 12 hours. Alternate therapy: · Phenytoin 1.5g IV/IO load + 100mg IV/IO every 8 hours · Phenobarbital 1.5g IV/IO load + 100mg IV/IO daily.
Consider nonconvulsive seizures in any TBI patient with GCS score ≤8 who is not improving with appropriate treatments. If not already placed, consider a definitive airway in any patient who experiences seizure. Perform after seizures are controlled.			
Management: Fever Control			
Maintain core temperature between 96°F and 99.5°F. Treat fever aggressively.	Remove patient from heat or sun. Remove clothing. Use surface cooling measures with misting and fan cooling	Apply cold packs to axillary, posterior cervical, and groin regions.	Acetaminophen 650mg every 4 hours PO or rectally for rectal temperature >99.5°F. Cold saline IV bolus if available.
Avoid NSAIDs, such as ibuprofen, naproxen, and ketorolac, because these agents may increase intracranial hemorrhage, if present.			
Management: Sodium Control			
Avoid hyponatremia. Mild hypernatremia optimal. Target sodium level: 145–160mmol/L.	Avoid administration of free water or hypotonic fluids.		Monitor serum sodium via laboratory blood samples. If patient is stable, check levels every 6 hours. In an unstable patient or one receiving HTS, check sodium level every 3 hours and adjust fluids as needed.
Numerous conditions can rapidly affect sodium levels in TBI patients. Monitor sodium and urine output whenever possible.			
Management: Blood Glucose Control			
Avoid both hypo- and hyperglycemia. Target blood glucose 100–180mg/dL.	Monitor for signs and symptoms of hypoglycemia. Allow patient to eat as long as they are able.		Check blood glucose every 6 hours with handheld glucometer. If <100mg/dL, give 25g (50mL) dextrose 50% (D50) IV/IO or 5tsp sugar/4tsp honey PO/NG.
Transportation			
TBI patients for ground and/or air transport to higher levels of care.	Dose sedative/analgesic medications, osmotic therapies, and/or benzodiazepines before any significant ground or air transport if possible.		Provide a detailed brief to the transport assets specifically highlighting any neurologic deficits and treatments and/or accommodations required during transport.
Neuromuscular blockers should only be used when the benefit outweighs the risks. Most patients should be transported in the supine position with the HOB elevated at least 30°. **For fixed-wing aircrafts: load patient with head to the front of the aircraft to minimize G-forces transmitted to the brain. **For altitudes >8000 ft, TBI patients are at risk of hypobaric hypoxia and high-altitude cerebral edema (HACE), which can worsen brain injuries.			

APPENDIX F: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e., "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Unexploded Ordnance (UXO) Management (CPG ID: 41)

This CPG provides details on the procedures to safely remove unexploded ordnance from combat patients, both loose and impaled, to minimize the risks to providers and the medical treatment facility while ensuring the best outcome for the patient.

INTRODUCTION

The purpose of this Clinical Practice Guide (CPG) is to provide details on the procedures to safely remove Unexploded Ordnance (UXO) from combat patients, both loose and impaled, to minimize the risks to providers and the Medical Treatment Facility (MTF) while ensuring the best outcome for the patient. Military ordnance, to include bullets, grenades, flares, and explosive ordnance, retained by a patient can be a risk to all individuals and equipment along the continuum of care. This is especially true from the point of injury to the first treatment facility. Ordnance can be categorized in many ways. For the purposes of patient care, it can be considered "loose," referring to items on the patient's gear or stored in their pockets, or "impaled" when it penetrates into the body.[1] While loose ordnance is fairly common among military patients and easy to address, embedded ordnance is rare and significantly increases the risk for the treatment team. Thirty-six reported cases of impaled ordnance from WWII through the Somalia conflict were discussed in a 1999 review article published in Military Medicine.[2] While cases have occurred in other non-US combat zones, this is held as the best-documented report of impaled ordnance. Of these cases, four were moribund upon arrival to advanced care and died while the other 32 survived their initial surgery. Of note, none of the 36 impaled UXO devices detonated or injured those caring for their patients. Four cases in Afghanistan and two in Iraq since 2005, with another US case reported from Pakistan in 2012, indicate that the risk of similar events is still present.[3] Prior planning, establishment of an standard operating procedure and realistic training are the best ways to prepare for managing these soldiers and avoid "on the fly" decision-making. However, if a patient arrives early on in the establishment of a MTF, expeditious and flexible management by medical leaders faced with the prospect of surgically removing UXO will have the greatest impact on patient and treating team survival. A discussion of steps to avoid accidental discharge of the ordnance and steps to mitigate risks to providers and the surgical facility follows. These protective principles may also be applied to the management of ordinance (e.g., suicide vest) found on non-military patients treated at medical facilities.

ORDINANCE TRIGGERING MECHANISMS

Fundamental to this discussion is a basic understanding of triggering mechanisms for those ordnance types most likely to become impaled in the body. These include mortars, Rocket Propelled Grenades (RPG) and 40 mm projectiles (rifle-launched grenades). A basic, unclassified understanding on how triggering and arming of the explosive round occurs will ensure the surgeon and surgical team avoid causing the ordnance to explode.

Previous reports of UXO reveal that the impaled round was some sort of propelled explosive device. These rounds basically consist of a propulsion system, a trigger mechanism, and a main explosive charge.

It should be assumed that a malfunction occurred causing the ordnance not to explode on impact into the patient. One should always assume that an inadvertent bypass of the safety mechanism or a malfunction could cause the ordnance to explode. All retained ordnance should therefore be considered "armed" or activated to a degree that final triggering of the fuse would cause the ordnance to explode. Fusing and triggering mechanisms vary by the type and variety of ordnance and may even vary within the same type of ordnance depending on where the ordnance was manufactured.

The trigger is generally located at the tip of the main explosive charge. This trigger activates a firing mechanism that impacts onto a percussion cap that activates a detonator. The detonator explodes, thereby igniting the primary explosive charge.

There are a variety of arming mechanisms for explosive ordnance. Typically, a mortar or rifle grenades (e.g., 40mm, M203) becomes armed and capable of exploding based on the number of rotations or spins completed after leaving the launching tube. Upon impact, a nail-like device located in the cone or nose of the device is

pushed down into a fissile explosive that detonates the actual explosive charge. Pressure on the nose of the mortar may also trigger the device to explode.

Piezoelectric crystals are also utilized as another arming mechanism. This is most commonly employed in an RPG. The rocket consists of a propulsion device and stabilizing fins for flight. The trigger utilizes a piezoelectric crystal at the tip of the projectile that generates an electric charge upon direct impact with the target. This charge ignites the detonator that explodes the primary charge. This crystal may also be activated upon exposure to light, electricity, or thermal energy. Therefore, the explosive device may be triggered by reorienting the patient, shining direct sunlight on the crystal, or providing a direct electric current to the device such as contact with an electro cautery device.

ROUTINE INITIAL MEASURES

All patients, regardless of whether they are friendly or enemy, require an initial inspection in order to find and remove all weapons and ammunition prior to entry into a transport vehicle or treatment facility. Screening of their bags and the litter is also essential to ensure that no "loose" ordnance or ammunition is brought into an area where they could be accidentally armed and detonated. Items should be given to the soldier's unit representatives or the area Explosive Ordnance Disposal (EOD) team or placed in a safe location (e.g., UXO pit) if these are not available. If "impaled" ordnance is identified during the initial inspection or triage, all non-essential individuals should go to a safe location and the higher command should be notified. In addition, it should be stated that a patient may have "impaled" ordnance that is not recognized until after initial Tactical Combat Casualty Care has been provided, ground or air transportation has been completed, or even during surgery. Therefore, individuals must always be prepared to execute the appropriate measures at any time during the continuum of patient care. Refer to Table 1 in Appendix A for more guidance.

TRANSPORT OF PATIENTS WITH SUSPECTED/CONFIRMED UXO

Casualties with suspected or confirmed "impaled" UXO should only be moved or evacuated if absolutely necessary. Whenever possible, surgical or diagnostic capabilities should be moved to the casualty's location in order to decrease the chance of vibration or travel over rough terrain resulting in UXO detonation. If movement is required, the patient should be extracted and positioned in the same position they were found as repositioning the patient may cause the ordnance to shift and trigger a charge. If the patient requires rotary wing transportation while the ordnance remains in place, it is essential to properly ground the patient to the helicopter to avoid static electricity causing the ordnance to trigger and explode. The aircrew must be consulted to ensure proper grounding of the patient to the aircraft.

COMMAND DECISION PRIORITIES AT COMPOUND WITH TREATMENT FACILITY

Safe removal of UXO requires significant coordination with local security, the base command element, and EOD personnel. Specific duties include:

BASE SECURITY AND COMMAND TEAM

The area where the patient is located should be secured or cordoned off. The time to identify this area is during the initial establishment of a treatment facility, long before a potential patient may arrive in need of care. Non-treating personnel should remain in protected location at a safe distance beyond the blast radius of the ordnance. All non-essential personnel, including medical providers, should move to that stand off point. The local commander should be informed that a patient with UXO is under medical care at the MTF or is due to arrive if prior notification is given.

EXPLOSIVE ORDNANCE DISPOSAL TEAM

It is imperative that EOD staff participate in mass casualty exercises involving UXO scenarios in order to develop robust procedures and guidelines. Furthermore, EOD can advise and assist in construction of a UXO barricade where the UXO can be removed and a second secured area to place the UXO once it has been removed following surgery. This is best done after the primary MTF has been established. The EOD unit contact information should be clearly posted in the surgical facilities administrative area and the phone number validated periodically. The EOD technician or other subject matter expert must provide input on the type of ordnance present, whether the explosive portion is still present, and the likelihood of detonation. All of this information must be factored into a risk benefit analysis. As the common impaled ordnance types have a number of variants, the EOD specialist can provide advice on specific concerns to prevent arming and detonating the device. In some instances, EOD technicians have assisted in removal of the ordnance during surgery.

PATIENT TRIAGE

During patient triage, the triaging officer must always inspect soldiers for loose UXO and impaled UXO. This must occur at all levels of care within the evacuation chain. If possible, the initial triage of the patients once at an MTF should be done outside the main treatment facility. Ideally, this is done nearby, but at a safe standoff distance. To assist with this, standard metal detector wands can be used with little risk of causing loose or impaled UXO to arm or detonate. During mass casualty situations, a patient with an impaled UXO could potentially endanger the staff, other patients, ground and rotary transport vehicles and drivers, and the main MTF. If there is a low probability of survival, they must be triaged to a delayed or expectant category, particularly when there are multiple casualties requiring surgical care. Comfort care, when appropriate, can be provided with the patient moved to a safe distance from the fixed or tented surgical facility.

ANCILLARY SURGICAL SITE

Safe removal of the UXO should be accomplished in an ancillary surgical site when time and casualty flow permit. This is done to avoid bringing the ordnance into the main Operating Rooms (ORs). This ancillary site should be established outside the main surgical facility where the removal of the ordnance can be expeditiously and safely performed. This site should also be well lit and have all the necessary anesthetic and surgical equipment readily available. The floor should be level and large enough to place a field operating table, a litter stand, or a litter on a wheeled litter system since it can be moved with minimal amount of personnel and can immediately be converted to a stable platform for performing surgery. Ensure that the set-up can accommodate the use of portable X-ray since it may be required to help identify the ordnance. Ideally, the site would provide a blast wall next to the table or litter that other medical staff can stand behind and be available for assistance or consultation. This location should be clearly established during the initial establishment of the treatment facility since it is difficult to identify and create a site in the midst of a patient with UXO impaled in their body. Avoid conducting this type of surgery in a confined space such as a contained bunker since the overpressure from a blast will only exacerbate the trauma from an explosion. Once the UXO has been removed, the patient can be moved to the main surgical facility to complete the operation.

X-RAY AND ULTRASOUND

Plain radiographs are generally considered safe with respect to potential inadvertent triggering of the UXO.[2] The patient should not be reoriented to obtain the films as any movement can inadvertently complete the arming or triggering mechanism and cause an explosion. The effects of ultrasound or CT scan on UXO are not documented in the literature.[4] Therefore; it is prudent to avoid these imaging modalities until studies confirm that they are safe.

SURGICAL INSTRUMENTS AND ADJUNCTS

Use of electrocautery, mechanical blood warmers, monitors, blood pressure gauges, infusers, or pumps should be minimized in order to reduce the risk of static electrical discharge.[5,6] Likewise, mechanical saws and drills that utilize electricity and pneumatics should be avoided in favor of non-powered manual saws due to concerns of discharge and vibrations.[6] In addition, surgical instruments, equipment, and supplies used for UXO surgery must be identified early on as part of the initial establishment or transfer of authority of a treatment facility. If available, these items should be placed in a container that can be rapidly moved to the ancillary surgical site. A list of items not in the container should be affixed to the top of the container so it can be collected Enroute to the ancillary surgical site. Do not use combustible agents in vicinity of patient (e.g., oxygen, alcohol-based solution, combustible volatile anesthetics).

OPERATING PERSONNEL

Personnel deemed not absolutely essential to achieve safe removal of the ordnance should be removed from the vicinity of the UXO.[7] Furthermore, all necessary equipment should be laid out in advance of the operation, eliminating the need for an OR technician whenever possible. A surgical assistant should only be used if it is absolutely necessary and the safe removal of the ordnance could not otherwise be accomplished. The UXO triage and operating team will vary from unit to unit and based on the specifics of the "impaled" ordnance. Each unit will need to identify who their primary UXO staff will be upon establishment of the treatment facility. This group of providers will need to periodically practice performing this task due to the complexities and stress involved.

Personnel typically volunteer to participate in these operations despite the significant danger. Final selection of the surgeon(s) to conduct the operation should be left up to the lead surgeon. It is imperative that the unit commander and the lead surgeon make every effort to limit the need for additional staff. This is done in order to minimize the risk to the surgical team, particularly in cases of mass casualties. Personnel participating in the surgery should gown and glove over ballistic protective equipment including safety glasses, helmet, and body armor with ballistic plates. An alternative approach is to perform UXO surgery while wearing an EOD bomb disposal helmet and suit (See Appendix B). This can be practiced in garrison and while deployed in collaboration with the local EOD unit. These suits have built in communications, heat-reducing technology, and are significantly better at protecting the entire body. All but the gloves can be worn providing protection to over 95% of the wearer's body.

ANESTHETIC CONSIDERATIONS

In most cases, general anesthetic will be used for these operations since it provides a more controlled environment.[7] For stable patients where the ordnance is impaled in an extremity, a nerve block is an acceptable alternative.[2] Use of supplemental oxygen during the operation to remove the ordnance should be limited in order to eliminate this additional combustible source. Ensure that the "D" size oxygen tank is behind the barrier, where the non-participating staff is located, to prevent it from exploding if the ordnance detonates. Consider having the anesthesia provider remote to the patient but able to view monitoring devices.

SURGICAL STRATEGY AND PRIORITIES

The guiding principle is to remove the ordnance by the most expedient means possible. This may require "en-bloc" resection of the tissue around the ordnance with amputation of the affected limb above the ordnance if this is deemed the quickest way to safely remove the ordnance. In general, impaled ordinance should be surgically exposed to a degree that will allow easy removal of the object in the same orientation as it lies in the body. Every effort should be attempted to avoid pushing forward or twisting the UXO during exposure or removal as this may set off triggering mechanism. Great care should be made to avoid banging or contacting the

ordnance with hands or surgical instruments. If ordnance is impaled into a limb, the extremity should be stabilized to avoid excessive vibration or movement that could complete the trigger. Simultaneous damage control operations for other injuries should be limited to life and or limb preserving operations. Delay definitive procedures until after the ordnance is safely removed. Once the UXO is removed, it should be gently handed off to an EOD expert or placed in explosive containment device. If the UXO placed in a containment device is in the vicinity of the patient, consider rapidly moving patient to safer location to complete procedure.

LATE FINDING OF UXO

Three of the six cases of impaled ordinance found in patients during the Global War on Terrorism were not recognized until the patient was in the OR. The impalement was unknown at the point of injury, transport, or initial evaluation by a Role 2 or Role 3 trauma teams since it was completely embedded in a body cavity or extremity with no exposed portions to alert the staff. The time and location when impaled UXO was initially recognized is not mentioned in previous reports. Intra-operative is not the ideal time to find the ordnance, but due to the nature of trauma and war wounds, this may be the case. Units must have a plan to address this. The core principles used in a known case of an impaled UXO should be followed. Minimal staff to remove the device is recommended, limit patient movement, and stop the use of medical equipment that may arm or detonate the device. The facility leadership and EOD team need to be notified as soon as possible. If the patient is stable, pause until EOD can confirm and identify the impaled device. Staff remaining to care for the patient should have their protective gear brought to them so they can don it rapidly. One of the biggest decisions is to stay within the facility or to relocate. This decision is complex and is dependent on multiple tactical and clinical factors. The medical treatment facility commander and senior surgeon must rapidly decide on the best course of action and ensure the safety of the staff while striving for survival of the patient. The goal is to care for the patient while preserving the personnel and equipment to care for current and future patients as well.

BIOLOGICAL AND CHEMICAL IMPALED UXO

While there are no documented cases of combat patients with loose or impaled UXO containing chemical or biological agents, it is conceivable that ordnance containing these agents could become impaled in a patient. Current doctrine states that it is a "command decision," on how to manage the patient.[1] However, it does not state if this is the local senior medical unit commander or local senior combatant commander that makes the decision whether to make the patient expectant or to provide full care. If the decision is made to provide full care and attempt to remove the agent containing UXO, individuals involved should be fully protected. All participating staff will need to wear available biological-chemical protective gear to include mask, body suit, boots, and gloves under their body armor if attempting to remove the ordnance. Ordnance containing chemical or biological agents usually has a much lower explosive force than traditional high-explosive or fragmentation ordnance to prevent destruction of the agents, and therefore the treating staff is at a lower risk of injury from a blast if the ordnance were to detonate. Therefore, there is more of a risk from contamination than blast when compared to a traditional high-explosive or fragmentation munitions. Agent containing ordnance should immediately be handed over to EOD followed by decontamination of the patient and medical staff when necessary before moving to the main treatment facility for further treatment.[1]

IMPALED UXO IN KIA PATIENTS

While the Armed Forces Medical Examiners System staff is unaware of any cases where a UXO was found impaled in a deceased US soldier since 2001, it has been reported in the world literature.[8,9] Since it has been recognized that many times the impaled ordnance is not identified until the patient is within a trauma treatment area of an MTF or in the OR, it again should be assumed that patients could die on the battlefield or in an MTF with unrecognized impaled ordnance. Therefore, it is recommended that all deceased individuals be screened

for impaled ordnance to prevent a catastrophic situation on the ground or in the air.[10] This can be accomplished by conducting a simple body cavity screening with a metal detecting wand, or an X-ray to include the torso, head, or injured extremities. If anything is found, the same precautions for a live patient should be taken to include having all nonessential people leave the threat area, notifying the local command, having security establish a perimeter, having EOD identify and remove the object, etc.

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

All patients with retained ordnance

INTENT (EXPECTED OUTCOMES)

- EOD consult documented for all patients in population of interest.
- Treatment occurred outside of emergency room/operating room.

PERFORMANCE/ADHERENCE MEASURES

- Number and percentage of patients in population of interest with EOD consult documented.
- Number and percentage of patients in population of interest who are evaluated and treated outside of emergency room/operating room.

DATA SOURCE

- Patient Record
- DoD Trauma Registry

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Director and PI Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local level with this CPG.

APPENDIX A : TABLE OF UNEXPLODED ORDNANCE (UXO) PRACTICES

UXO Situational Practices
▪ Establish triage/search/blast contaminant area external to medical treatment facility (MTF) or establishment of facility.
▪ Upon discovery of UXO, immediately evacuate all non-essential personnel and move to a safe distance or protected one.
▪ Notify Explosive Ordinance Disposal team and local command authority.
▪ Using appropriate personal protective equipment, if possible move patient to a location separate from the MTF for evaluation and treatment.
▪ Minimize number of personnel involved in patient treatment, use of electrical equipment that may detonate UXO (e.g., electrocautery) and presence of additional combustible agents (e.g., oxygen, alcohol-based solutions, combustible volatile anesthetic agent).

APPENDIX B: UXO PERSONAL PROTECTION EQUIPMENT

APPENDIX C: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

How to Manage Mechanical Ventilation When Using the Universal Portable Anesthesia Complete Vaporizer, 26 Dec 2021

I. Introduction

A. *This Clinical Practice Guideline (CPG) will clearly demonstrate in a step-by-step fashion the proper setup of the UPAC to each of the fielded ventilators, allowing anesthesia providers across all services to deliver safe, effective anesthesia to our warfighters.*

B. Anesthesia providers in Forward Resuscitative Surgical Teams (FRSTs) have relied on the Impact Uni-Vent Eagle 754 ventilator (Impact 754) to manage mechanical ventilation when using the Universal Portable Anesthesia Complete (UPAC) vaporizer. In support of modernizing forward surgical care, including the deployment of FRSTs, the military now fields new ventilators across the services. These ventilators include the Impact Uni-Vent 731 (Impact 731), HAMILTON T-1, and SAVe II. The Impact 731 and HAMILTON-T1 are the most readily available to FRSTs. While the SAVe II is available to some FRSTs, it is not recommended for long-term use and should only be used when other ventilators are not available. It is likely that many anesthesia providers have not worked with these new ventilators, and do not have the knowledge or access to reliable references/resources on the proper mating of the UPAC to a specific ventilator.

C. The CPG will follow a simple, easy to read format devoid of extraneous details. Each ventilator will have a section detailing complete start-to-finish setup of the UPAC to the ventilator. There will be detailed, labeled photographs with captions to assist the reader. Additionally, there will be troubleshooting tips at the end of each ventilator's section when applicable.

D. This CPG will serve as an invaluable resource to military anesthesia providers at home and abroad. There is no other known resource of its kind available to date, and it is a resource that can be easily adapted and utilized in the ever changing operational domain. The CPG will equip anesthesia providers with the knowledge and confidence to provide the highest quality care possible and assist our service members return to the fight.

II. UPAC Draw-Over Vaporizer

A. Standard equipment

Figure 1. Disassembled UPAC components. 1) UPAC case 2) UPAC vaporizer 3) Facemask 4) UPAC patient circuit tubing 5) Oxygen concentrator tubing and self-inflating bag tubing 6) T connector 7) Oxygen reservoir dust cap 8) Unidirectional E valve 9) Self-inflating bag 10) Oxygen tubing

Comments: Disassembled UPAC standard components

Figure 2. UPAC basic set

Comments: The UPAC vaporizer, UPAC patient circuit tubing, oxygen tubing, and facemask are known as the basic set. The basic set is required for use with each ventilator. Note that the oxygen concentrator and self-inflating bag tubing, T connector, oxygen reservoir dust cap, unidirectional E valve, and self-inflating bag from Figure 1 are not required items when using the UPAC with a ventilator. If positive pressure ventilation is needed without using a ventilator, use a separate self-inflating ventilation device (Ambu-bag) after disconnecting the patient from the UPAC-ventilator circuit.

Figure 3. Basic set with vaporizer oxygen inlet attached. 1) Supplemental oxygen connection.

Figure 4. UPAC vaporizer. 1) Vaporizer inlet 2) Concentration dial 3) Vaporizer outlet 4) Universal concentration chart 5) Supplemental oxygen inlet 6) Liquid anesthetic site glass 7) Fill port 8) Vaporizer stand

Comments: UPAC vaporizer details. When using the UPAC in a push-through configuration (as demonstrated in all four ventilator cases) the UPAC patient circuit tubing from the basic set is connected to the vaporizer inlet (Figure 4-1) and the standard ventilators' patient circuits are attached to the vaporizer outlet (Figure 4-3). C-clamps are also needed to secure the vaporizer stand to the work surface due to the top heavy nature of the vaporizer.

III. Impact 754 Ventilator

A. Required equipment

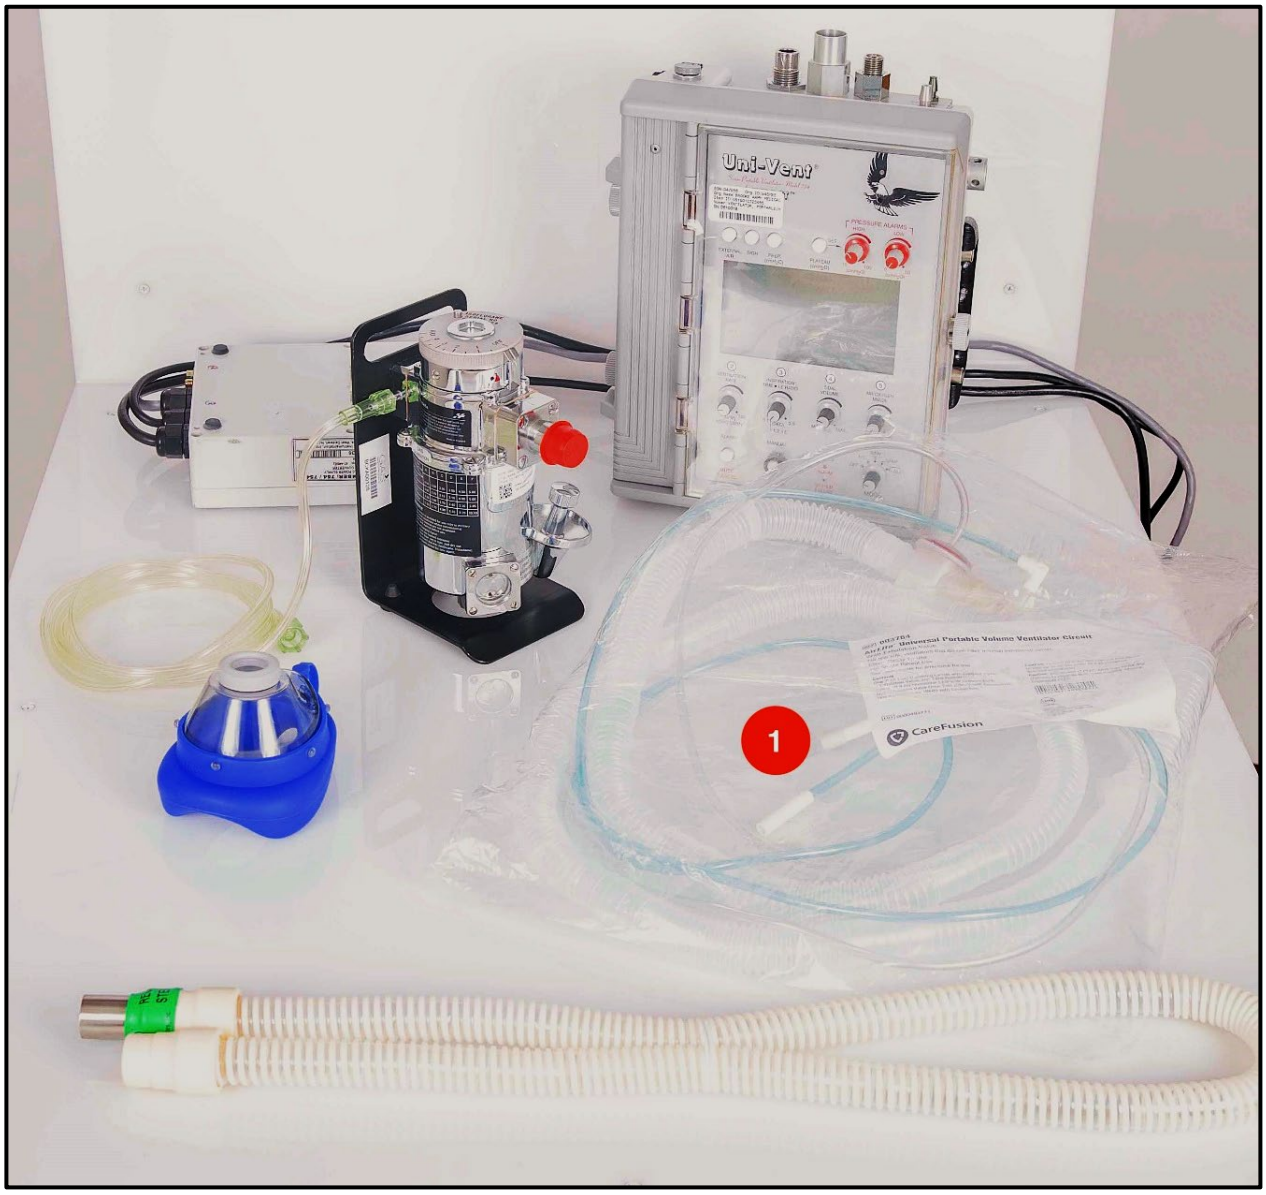

Figure 5. Impact 754 ventilator standard equipment set with patient circuit and UPAC basic set.
1) Patient circuit

Comments: The Impact 754 ventilator circuit will function with the Impact 731 and SAVe II ventilators.

Figure 6. Impact 754 power source. 1) Power connection for ventilator

Figure 7. Top view of Impact 754. 1) Attachment for standard circuit expiratory check valve 2) Attachment for standard circuit pressure transducer 3) Attachment for UPAC patient circuit tubing from the basic set

Comments: The UPAC patient circuit tubing from the basic set will connect to the vaporizer inlet (Figure 4-1).

Figure 8. Top view of patient connections for Impact 754. 1) Expiratory check valve tubing connected (clear tubing) 2) Pressure transducer tubing connected (blue tubing) 3) UPAC patient circuit tubing from the basic set

Comment: The pressure transducer tubing (blue) should be a different color than the expiratory check valve tubing (clear). The expiratory check valve tubing also has a textured collar at the end. If using

pipeline supply oxygen (55 psi standard) to the Impact 754, the auxiliary oxygen inlet on the UPAC (Figure 4-5) must remain occluded during use.

B. Connection to UPAC

Figure 9. Connection of UPAC patient circuit tubing from the attachment for UPAC patient circuit tubing from the basic set to the vaporizer inlet (Figure 4-1)

Comment: The UPAC patient circuit tubing metal-fitting end will connect to the vaporizer inlet.

C. Waste anesthetic gas scavenger setup

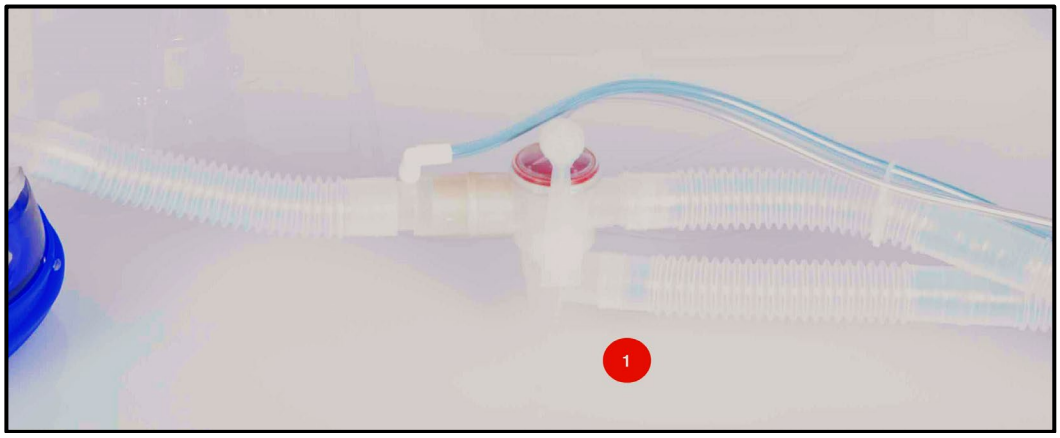

Figure 10 Waste anesthetic gas tubing connection to expiratory check valve of standard Impact 754 circuit. 1) Waste anesthetic gas tubing connection

Comments: Any standard diameter respiratory tubing (22mm female connection) will fit onto the swivel adapter directly beneath the expiratory check valve. This scavenger tubing should be routed out of the OR area, and *not* attached to any direct suction source (maintain passive waste anesthetic gas scavenging). Recommend using wire mesh or the standard UPAC dust cap (Figure 1-7) to prevent debris or insects from entering and occluding waste anesthetic gas tubing.

D. Full setup

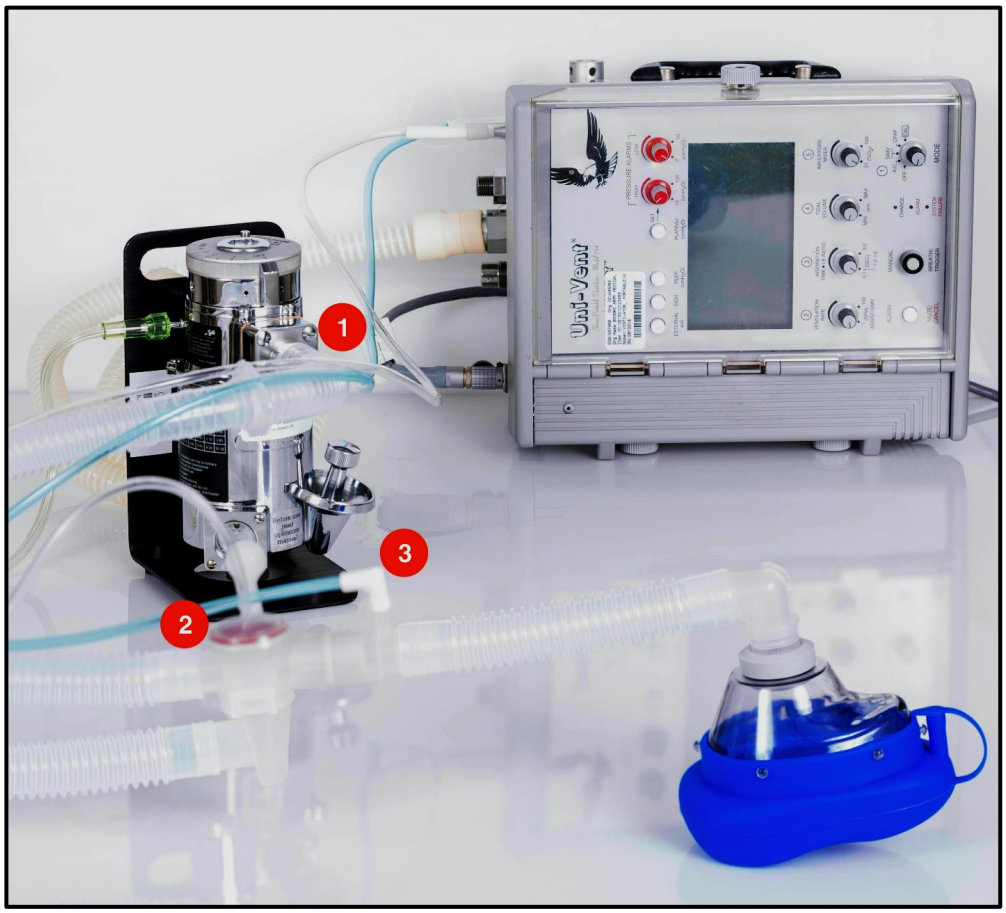

Figure 11. Complete setup of Impact 754 with UPAC. 1) Impact 754 circuit connected to UPAC outlet 2) Expiratory check valve 3) Pressure transducer

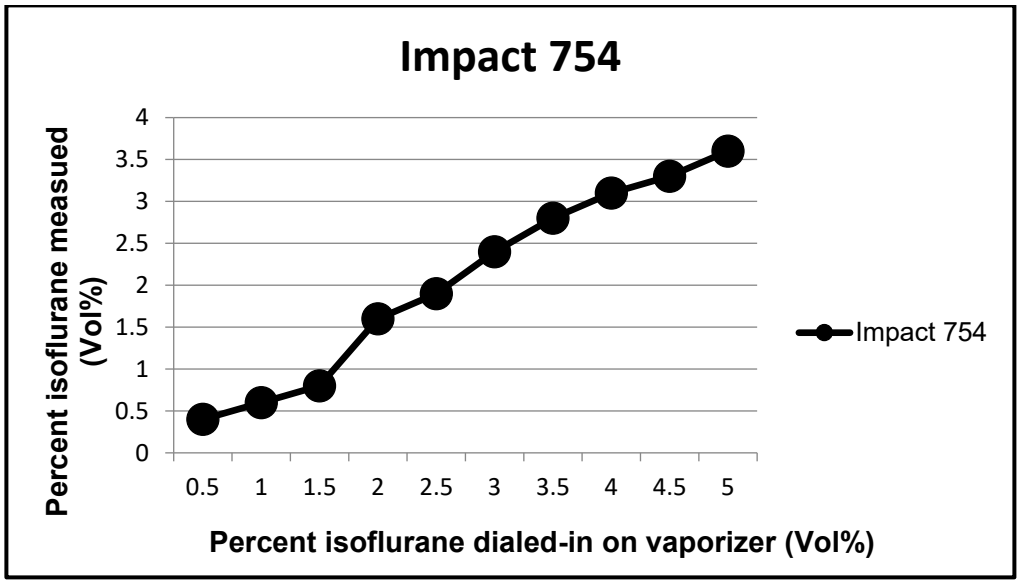
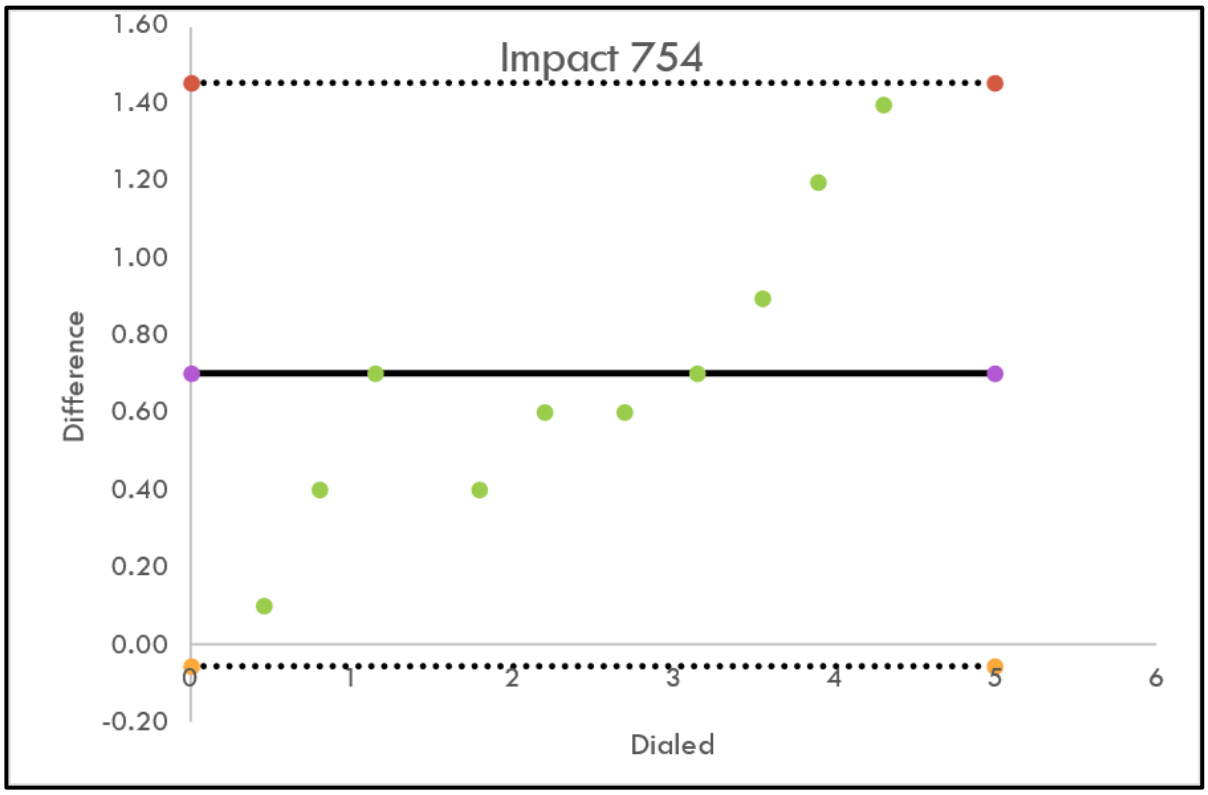
Comments: None

E. Expected UPAC vaporizer delivered agent concentrations (isoflurane shown)



F. Bland-Altman curve graph for isoflurane



G. Troubleshooting

Due to the limited visibility of the Impact 754 LCD screen, the use of a head lamp or flashlight is strongly encouraged. An external light source is not included in any discussed equipment set.

IV.Impact 731 Ventilator

A. Required equipment

Figure 12. Impact 731 ventilator. 1) Impact 731 2) Power cord 3) Standard Impact patient circuit and UPAC basic set

Comments: None

Figure 13. Top view of patient connections for Impact 731. 1) Power connection 2) Attachment for UPAC patient circuit tubing from the basic set 3) Attachment for standard circuit expiratory check valve 4) Attachment for standard circuit pressure transducer

Comments: None

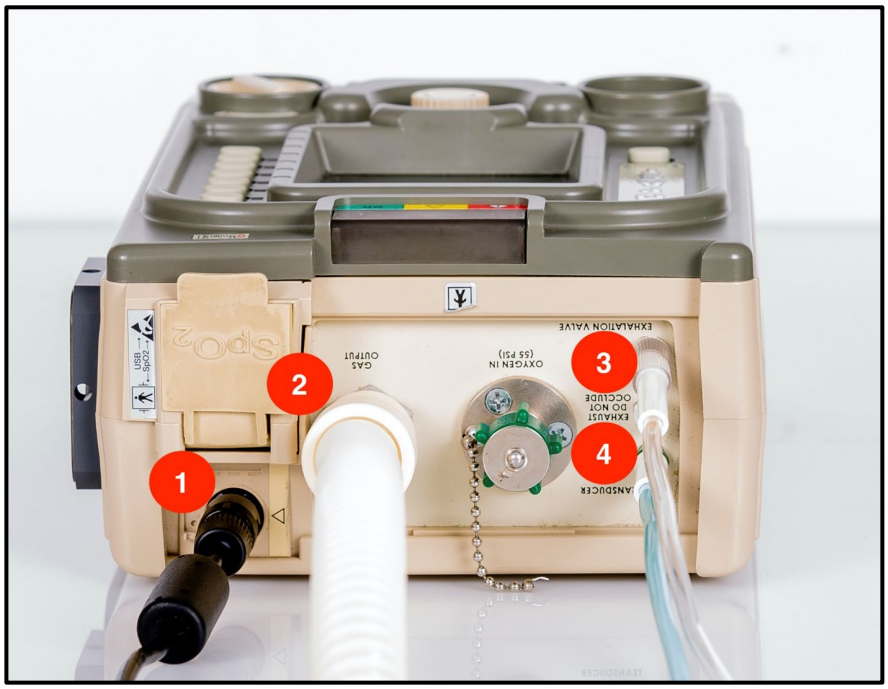


Figure 14. Top view of patient connections for Impact 731. 1) Power cord connected 2) Outlet connection to vaporizer via UPAC patient circuit tubing from the basic set 3) Expiratory check valve tubing connected (clear tubing) 4) Pressure transducer tubing connected (blue tubing)

Comments: As with the Impact 754, the pressure transducer tubing (blue) should be a different color than the expiratory check valve tubing (clear) on the Impact 731. The expiratory check valve tubing also

has a textured collar at the end. If using pipeline supply oxygen (55 psi standard) to the Impact 731, the auxiliary oxygen inlet on the UPAC (Figure 4-5) must remain occuded during use.

B. Connection to UPAC

Figure 15. Connection of UPAC patient circuit from the basic set (Figure 7-3) from the Impact 731 ventilator outlet (Figure 13-1) to the UPAC vaporizer inlet (Figure 4-1)

Comment: The UPAC patient circuit tubing metal-fitting end will connect to the vaporizer inlet.

C. Waste anesthetic gas scavenger setup

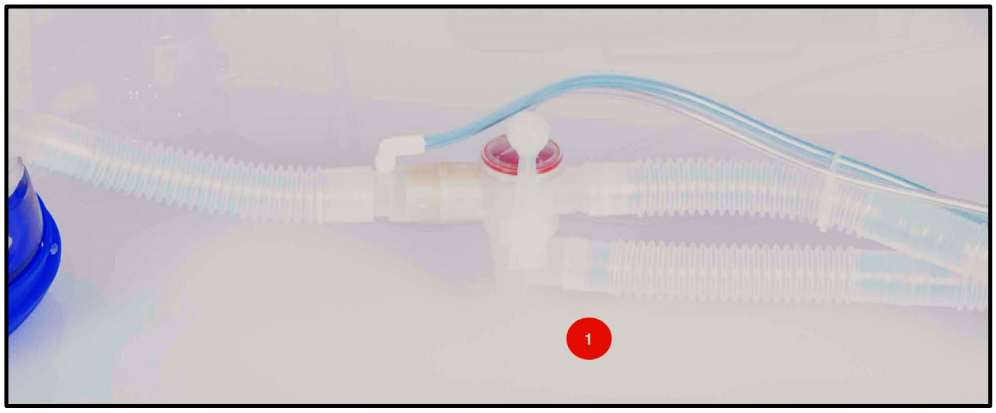

Figure 16. Waste anesthetic gas tubing connection to expiratory check valve of standard Impact 731 circuit. 1) Waste anesthetic gas tubing connection

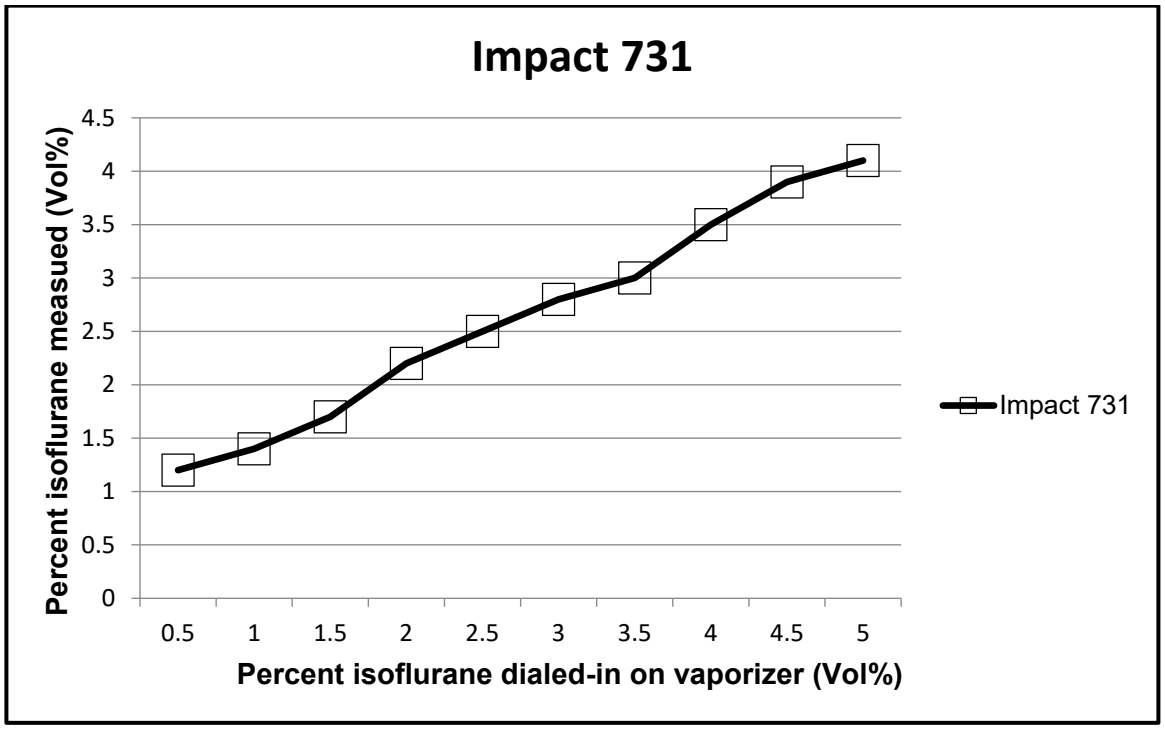
Comments: Any standard diameter respiratory tubing (22mm female connection) will fit onto the swivel adapter directly beneath the expiratory check valve. This scavenger tubing should be routed out of the OR area, and *not* attached to any direct suction source (maintain passive waste anesthetic gas scavenging). Recommend using wire mesh or the standard UPAC dust cap (Figure 1-7) to prevent debris or insects from entering and occluding waste anesthetic gas tubing.

D. Full setup

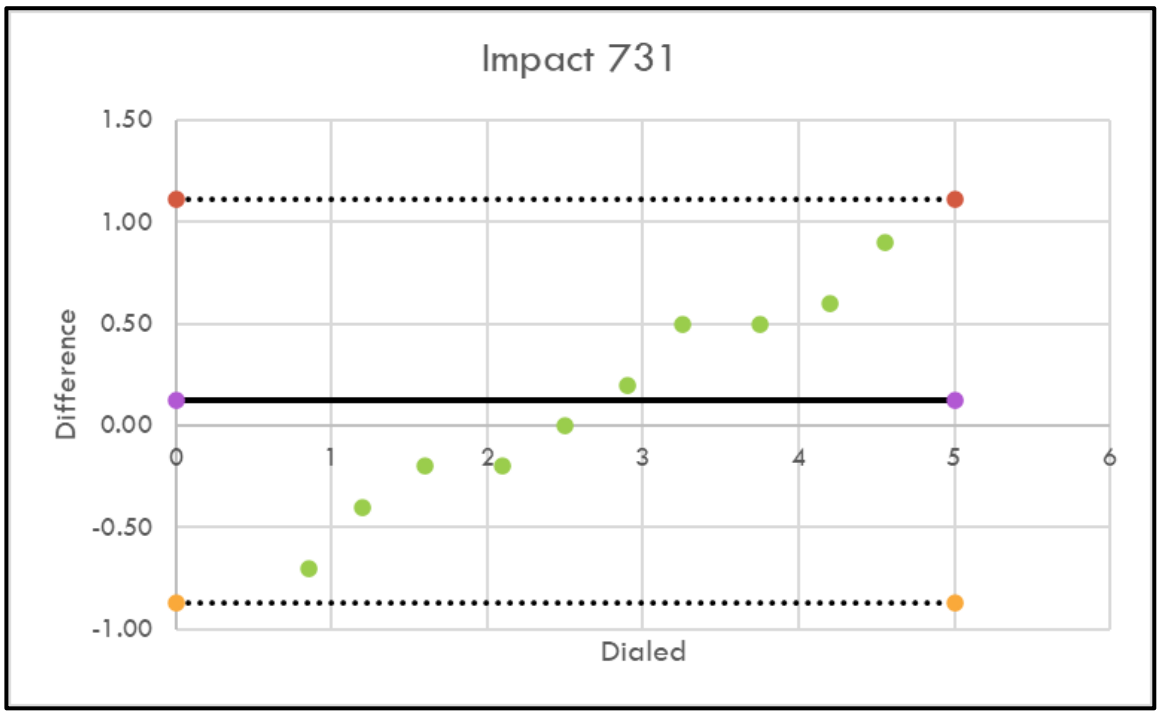
Figure 17. Complete setup of Impact 731 with UPAC. 1) Impact 731 circuit connected to UPAC outlet 2) Expiratory check valve 3) Pressure transducer

Comments: None

E. Expected UPAC vaporizer delivered agent concentrations (isoflurane shown)



F. Bland-Altman curve graph for isoflurane



G. Troubleshooting:

The standard circuits for the Impact 754 are completely compatible with the Impact 731.

V. HAMILTON T-1 Ventilator

A. Standard equipment

Figure 18. HAMILTON T-1 ventilator with standard patient circuit

Comments: Please refer to the HAMILTON T-1's operating instructions for pre-use checks and calibration.

B. Connection to UPAC

Figure 19. Side view of patient connections for HAMILTON T-1. 1) Outlet to UPAC 2) Inlet from patient

Comments: None

Figure 20. Expiratory valve diaphragm on ventilator circuit connection. 1) Expiratory valve diaphragm

Comments: The ventilator will not function if this valve is omitted before circuit assembly.

Figure 21. Side view of patient connections for HAMILTON T-1 with scavenger tubing. 1) HAMILTON T-1 outlet connection to UPAC via UPAC patient circuit tubing from the basic set 2) Input from patient expiratory limb of standard circuit 3) Expiratory check valve control connection (clear tubing) 4) Pressure transducer connection (blue tubing) 5) Scavenger tubing connected to expiratory check valve

Comments: The corrugated scavenger tubing is *not* included in the HAMILTON T-1 circuit. ***Respiratory tubing with a standard internal diameter of 22mm is needed to facilitate this portion of the setup.*** This scavenger tubing should be routed out of the OR area, and *not* attached to any direct suction source (maintain passive waste anesthetic gas scavenging). Recommend using wire mesh or the standard UPAC dust cap (Figure 1-7) to prevent debris or insects from entering and occluding waste anesthetic gas tubing.

Figure 22. Side view of patient connections for HAMILTON T-1 with expiratory tubing from HAMILTON T-1 standard breathing circuit to ventilatory expiratory check valve. 1) HAMILTON-T1 expiratory tubing

Comments: None

C. Waste anesthetic gas scavenger setup

Figure 23. Side view of scavenger tubing connection for HAMILTON T-1. 1) Scavenger tubing (Expiratory limb of HAMILTON T-1 standard breathing circuit omitted for emphasis on scavenger tubing connection.)

Comments: Due to the angle of the scavenger outflow, ***the right side of the HAMILTON T-1 ventilator should be elevated slightly to prevent kinking and occlusion of the scavenger corrugated tubing***. It is possible to attach one of the 90-degree elbows that are included with the HAMILTON T-1 set if the connection is wet with isopropyl alcohol in advance of assembly.

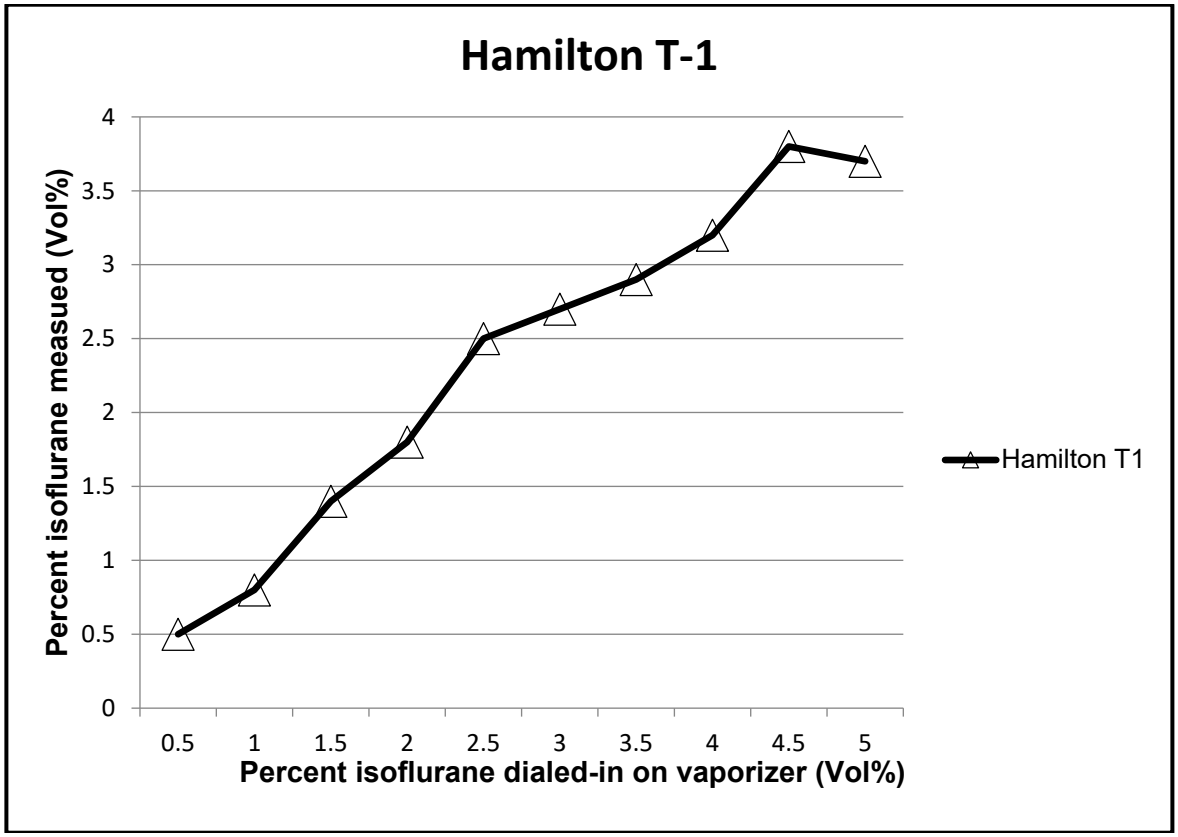
D. Full setup

Figure 24. Complete setup of HAMILTON T-1 with UPAC
Comments: None

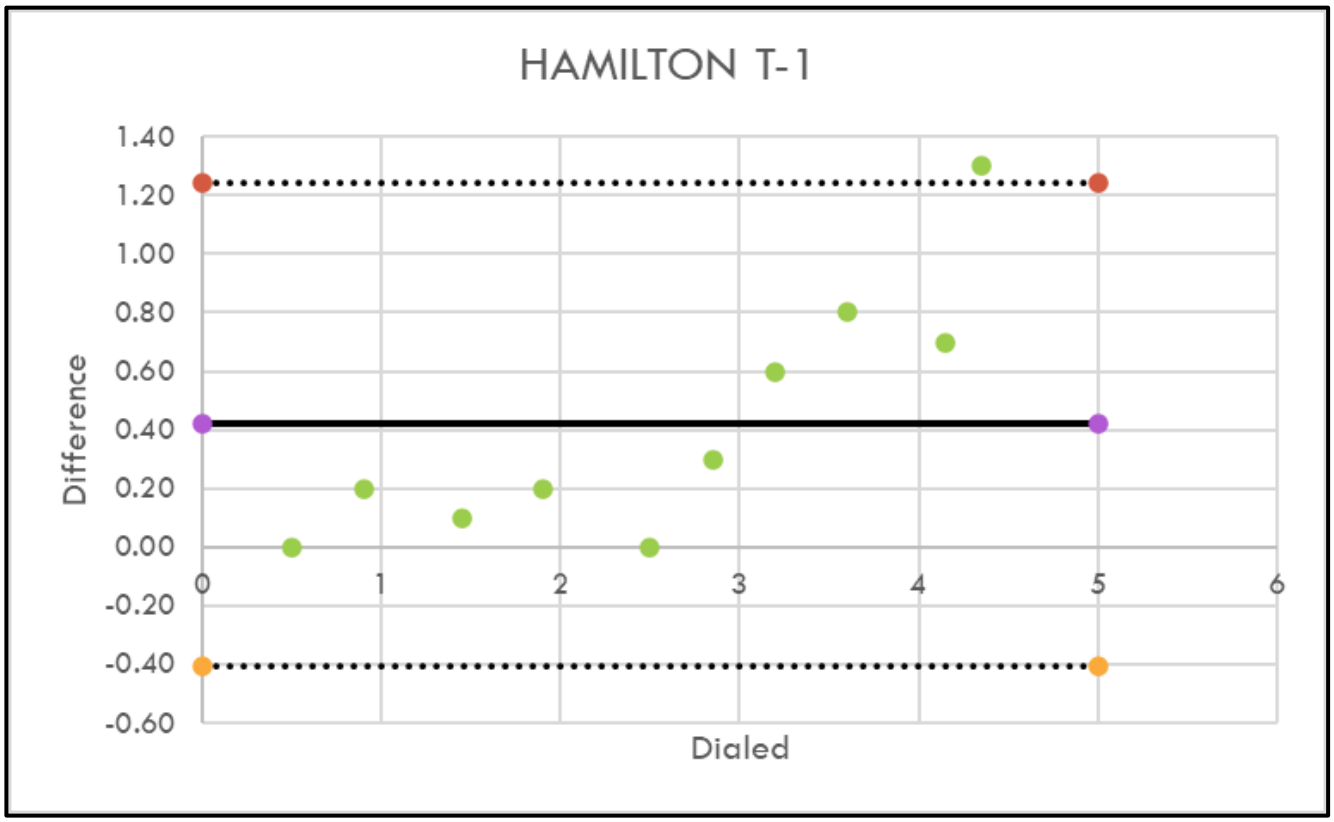
Figure 25. Side view of complete setup of HAMILTON T-1 with UPAC. 1) Bend and kinking of the scavenger tubing

Comments: Notice the bend and kinking of the scavenger tubing on the right side of the ventilator. ***The risk of scavenger and expiratory limb occlusion and barotrauma is relevant.***

E. Expected UPAC vaporizer delivered agent concentrations (isoflurane shown)



F. Bland-Altman curve graph for isoflurane



G. Troubleshooting:

Recommended best practice is to complete the pressure and flow sensor calibration sequence after complete assembly of the HAMILTON T-1 with the UPAC.

NOTE: Failure to complete these checks with the UPAC dial in the "off" position and the auxiliary oxygen inlet (Figure 3-1) on the UPAC occluded will result in a failed check error message on the HAMILTON T-1 screen.

VI.SAVe II Ventilator

A. Required equipment

Figure 26. Basic set and SAVe II ventilator. 1) UPAC corrugated tubing and scavenger tubing 2) SAVe II ventilator 3) Power cord 4) Standard circuit patient connection 5) Corrugated extension at patient connection

Comments: The scavenger tubing is not a standard tubing to the SAVe II.
***Long-term use of the SAVe II should be avoided in critical patients. It should only be used when other ventilators are not available.*

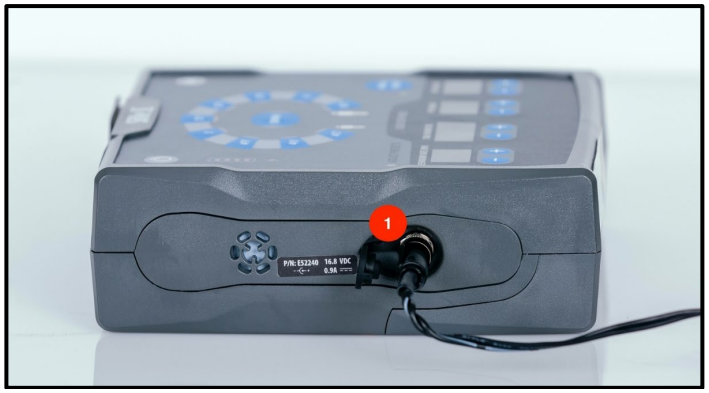


Figure 27 SAVe II ventilator power. 1) Power connection

Comments: None

Figure 28. SAVe II ventilator with standard patient circuit attached

Comments: The standard circuit from the Impact 754/731 has antectodal reports of compatability with the SAVe II.

Figure 29. Top view of patient connections for SAVe II. 1) Outlet connection to UPAC via UPAC patient circuit tubing from the basic set 2) Pressure transducer tubing (blue) 3) Expiratory check valve tubing (clear)

Comments: None

B. Connection to UPAC

Figure 30. SAVe II with UPAC connected

Comments: Note that scavenger tubing is not connected.

C. Waste anesthetic gas scavenger setup

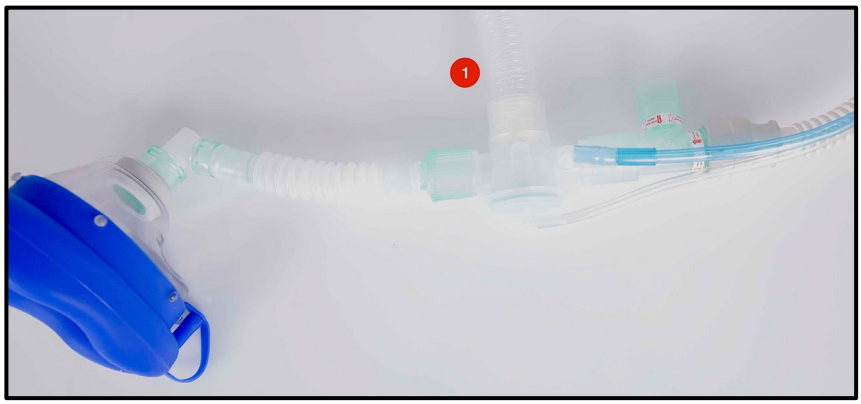

Figure 31. SAVe II standard circuit with corrugated tubing for scavenging connected. 1) Corrugated tubing for scavenging

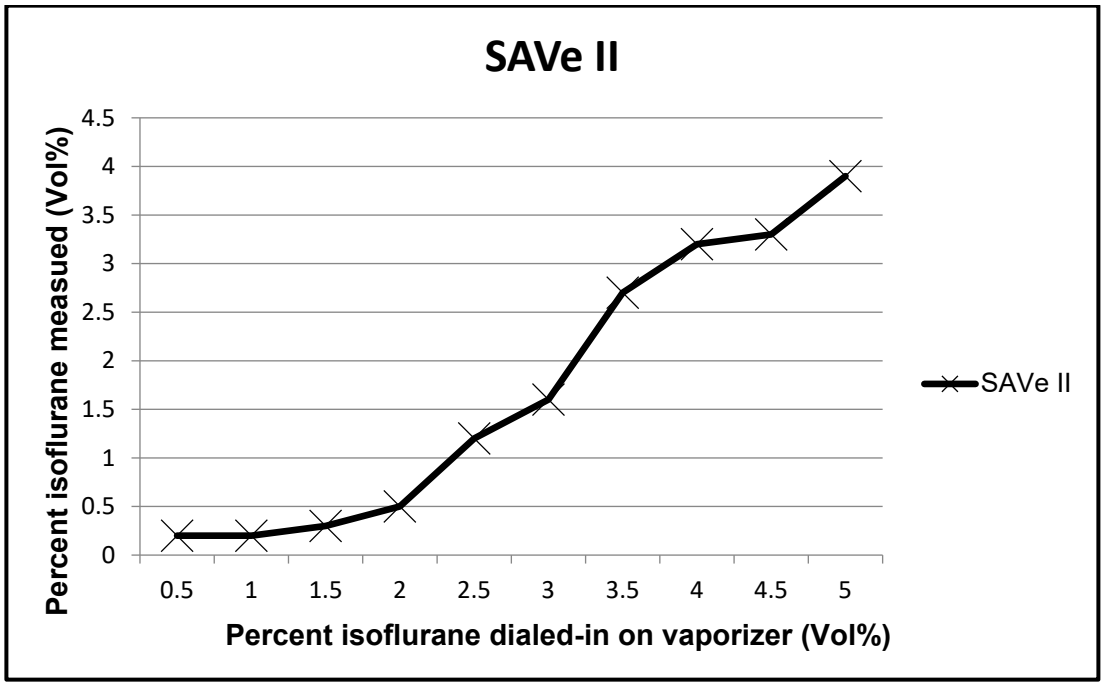
Comments: ***The outer diameter of the tubing must be increased by wrapping one-inch silk tape around one end in order for it to seat beneath the expiratory check valve of the SAVe II circuit.*** This scavenger tubing should be routed out of the OR area, and *not* attached to any direct suction source (maintain passive waste anesthetic gas scavenging). Recommend using wire mesh or the standard UPAC dust cap (Figure 1-7) to prevent debris or insects from entering and occluding waste anesthetic gas tubing.

D. Full setup

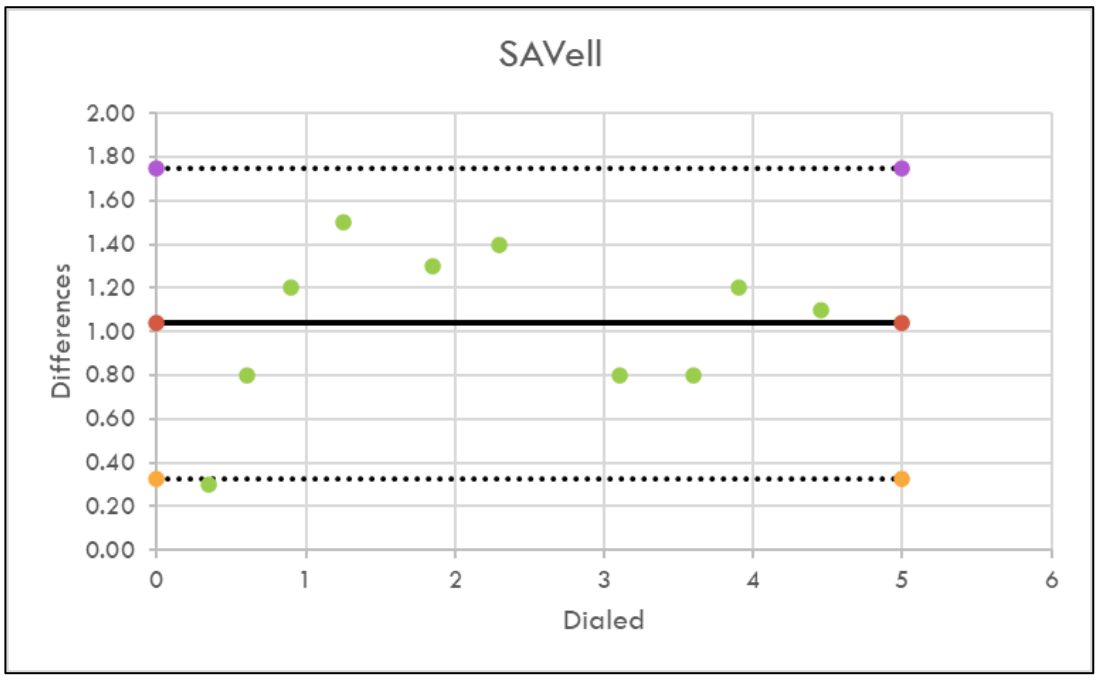
Figure 32. Complete setup of SAVe II with UPAC and scavenger tubing attached. 1) Scavenger tubing

Comments: The outer diameter of the tubing must be increased by wrapping one-inch silk tape around one end in order for it to seat beneath the expiratory check valve of the SAVe II circuit.

E. Expected UPAC vaporizer delivered agent concentrations (isoflurane shown)



F. Bland-Altman curve graph for isoflurane



G. Troubleshooting:

The noise from the compression chamber increases dramatically as tidal volumes and rates increase. Noise discipline as well as normal verbal communication will likely be compromised in these situations.

Appendix: Frequently Asked Questions about Managing Mechanical Ventilation and Using the UPAC Vaporizer in Deployed Settings

Purpose

This addendum serves to address frequently asked questions (FAQs) the authors received from anesthesia providers practicing in deployed settings.

FAQs

Q: Is the UPAC and mechanical ventilation setup meant for use during induction of a non-intubated patient?

A: No. The setup outlined in this CPG cannot serve as a substitute anesthesia machine and is meant for use post-intubation. If the provider wishes to use the UPAC during induction, they must use a self-inflating bag to provide manual ventilation to the patient and confirm endotracheal intubation. The provider must also emerge the patient using a self-inflating bag or by setting the ventilator on "spontaneous" (if available) and emerging with the UPAC in the "Off" dial position.

Q: Does the CPG address the use of the UPAC vaporizer in a pull-through configuration?

A: No, the current version of the CPG represents the use of the UPAC in a push-through configuration, meaning the ventilator pushes air and oxygen over the volatile agent in the UPAC for delivery to the patient.

Q: Why is the use of the UPAC in a pull-through configuration not discussed in this CPG?

A: While the Impact 731 and 754 have been used by multiple anesthesia providers in the pull-through configuration in deployed and training environments successfully, the effect of introducing anesthetic vapor into the impeller-driven compression chamber of the Hamilton T1 is unknown. Based on communication with the engineering branch at Hamilton Medical, using the T1 and UPAC in this configuration would be considered "off label use" by the manufacturer. Bench research studies are currently being designed to address this knowledge deficit, and will be relayed in a future addendum.

Q: Are there deployed transport ventilators that will preclude using the UPAC in a pull-through configuration?

A: Yes. The civilian version of the Hamilton T1, which has been furnished to deploying surgical teams lacks the air inlet fitting on the back of the ventilator (where an NBC filter could also be attached). Instead, there is simply a rectangular cutout to allow for air entry into the compression chamber of the T1 (see image below).

HAMILTON-T1 transport ventilator | Hamilton Medical (hamilton-medical.com)

This difference eliminates the 22mm fitting required to connect the UPAC patient outlet to the air inlet on the T1, as seen in the image below.

22mm NBC Filter Adapter. Author provided image.

Q: In what ways can supplemental oxygen be added to the delivered gases?

A: Low pressure oxygen, as delivered from a deployable oxygen concentrator, can be added via the supplemental oxygen inlet fitting on the side of the UPAC (see Figure 3 (1) in the above CPG) or the yellow oxygen inlet fitting on the circuit attachment side of the Hamilton T1. High pressure oxygen from a cylinder with a regulator can be attached via the diameter index safety system (DISS) fitting on the ventilators discussed in the CPG (except for the SAVeII).

Q: What are the FiO2 and flow limitations?

A: If the oxygen concentrator being used in a deployed setting has a maximum flow rate of 5 liters per minute, the delivered FiO2 will vary from a high of 0.78 FiO2 (78%) at a minute ventilation of 2.5 liters per minute to a low of 0.44 FiO2 (44%). These values are based on a recent bench research study's unpublished secondary analysis data. If higher flow rates are possible, these values will increase as well.

PURPOSE

These guidelines are intended to provide a basic management approach after a potentially concussive event using the specific plasma biomarkers for traumatic brain injury (TBI) on the iSTAT Alinity. This guidance does not apply to other brain injury devices or TBI biomarkers. This CPG is intended to complement and build upon the existing *DoD Instruction (DoDI) 6490.11 DoD Policy Guidance for Management of Mild Traumatic Brain Injury/Concussion in the Deployed Setting*.

BACKGROUND

- Between 2000 and 2019 TBI affected over 417,503 service members worldwide, with 88% of those injuries being classified as mild (mTBI), also known as concussion.[1] Common sequelae after mTBI include: headache, visual impairment, Post-Traumatic Stress Disorder (PTSD), depression and cognitive disorders; individuals with a mTBI are at increased risk of post-traumatic stress.[2-4] Secondary to these effects, only 70% of individuals diagnosed with mTBI return to full duty.[5]
- Individuals with mTBI typically have a normal (or negative) head CT. The purpose of head CT in an individual with suspected mTBI is to rule out a more severe injury requiring a higher level of care. For example, intracranial hemorrhage requires inpatient observation and, if severe, neurosurgical intervention. In civilian settings, approximately 6-8% of individuals with suspected mTBI at initial evaluation have evidence of intracranial hemorrhage and 1-2% require neurosurgical intervention.[6,7]
- CT scanners are typically available in theater at Role 3 facilities and select enhanced Role 2 facilities. The decision to transport a casualty from Role 1 or Role 2 to Role 3 for a head CT can have significant implications for the safety of the flight crew and mission accomplishment. Medical decision making should include an assessment of operational risk.
- An evaluation of the DoD Trauma Registry (DoDTR) suggests 68% of casualties identified as having mTBI were evacuated to the Role 3 for a head CT and 41% to Role 4, with approximately 78% of those Soldiers being returned to duty.[8] However, it is important to recognize the DoDTR only contains a subset of more severely injured Service Members with an mTBI in theater. Nonetheless, the data suggests that many evacuations for head CT may be avoided.
- The Military Acute Concussion Evaluation 2 (MACE2) provides guidance in the initial evaluation and management of individuals with (GCS score 13-15 in the deployed setting. It includes an assessment of "red flags" to determine the need for head CT and evacuation. In addition, the New Orleans Criteria and the Canadian Head CT rule also aid in identifying individuals most likely to benefit from head CT. None of these rules have been validated in the deployed setting.[9,10]
- Glial Fibrillary Acidic Protein (GFAP) and Ubiquitin Carboxyl-terminal Hydrolase L1 (UCH-L1) are contained within cells in the central nervous system and released upon neuronal damage. Higher levels indicate worsening neuronal injury.
- In January 2021, the U.S. Food and Drug Administration (FDA) approved a plasma biomarker for TBI, the i-STAT TBI Plasma Cartridge with the i-STAT Alinity System. This semi quantitative assay detects levels of GFAP and UCH-L1 in plasma. A facility with a lab section can perform the TBI plasma biomarker test. A result of "not elevated" on this test has a Negative Predictive Value approaching 100% for determining the absence of acute traumatic intracranial lesions on head

CT imaging. (See Appendix C Figure 1 for further information.) This assay is also known as the *Analyzer, Traumatic Brain Injury (ATBI) System.*

- Since this biomarker is performed on plasma, the test can only be used in a clinical laboratory setting with the capability to produce and test a plasma sample. Key logistical requirements include a centrifuge, refrigerated storage for cartridges, and frozen storage for calibration fluid. Ongoing product development efforts are focused on developing this into a test that can be performed on whole blood which will enable the use of the biomarker in a wider array of settings.

***NOTE**: Related clinical practice guidelines (CPGs): VA/DoD Clinical Practice Guideline for the Management of Concussion-Mild Traumatic Brain Injury, JTS Neurosurgery and Severe Head Injury*

STRUCTURE TO SUPPORT OPTIMAL USE OF TBI BIOMARKER

To minimize risks associated with use of this novel capability, we recommend a highly controlled rollout of the TBI biomarker. Each theater should restrict interpretation of test results and evacuation decisions to a select number of designated TBI biomarker consultants typically co-located at the Role 3. These individuals possess experience in evaluation, triage, and management of TBI in the acute setting and are knowledgeable in the clinical application of TBI biomarker values. The Theater Trauma Medical Director (TMD) is responsible for directing this overall effort but will normally yield clinical decision-making capacity to the neurosurgeon or other neurospecialist if available. Concurrent and standardized record-keeping using the Biomarker Data Collection Tool (Appendix D) is a must. This tool succinctly communicates mechanism, signs, symptoms, exam findings, TBI biomarker values, clinical decisions, evacuation priority, and concordant CT results or outcomes. The consultant is responsible for supporting the forward provider in execution of the TBI Biomarker Algorithm (Appendix A), use of TBI biomarker results, and disposition of the patient. When a negative TBI biomarker test guides a decision to keep the patient at the forward location, the consultant or TMD should remain engaged with that provider until no longer necessary. We recommend the consultants be responsible for completing the Biomarker Data Collection Tools. As the individual responsible for this TBI Biomarker Program, the TMD will ensure the Biomarker Data Collection Tools are submitted to Joint Trauma System (JTS).

INITIAL EVALUATION

Casualties should initially be evaluated and resuscitated based on JTS guidelines, Advanced Trauma Life Support (ATLS) principles, and Tactical Combat Casualty Care (TCCC) protocols after an acute injury, which may include a potentially concussive event (PCE). PCEs are defined in DoDI 6490.11 and include:

- involvement in a vehicle blast event, collision, or rollover;
- presence within 50 meters of a blast (inside or outside);
- a direct blow to the head or witnessed loss of consciousness; and
- exposure to more than one blast event.

The DoD classification of head injury as mild, moderate or severe includes the results of imaging and reports of symptoms for up to 7 days. Thus, for the purposes of initial evaluation in the field, the GCS is the most appropriate initial assessment and also has prognostic implications in the combat environment.

Head injured casualties are initially classified according to their GCS score:

- Mild: GCS 13-15
- Moderate: GCS 9-12
- Severe: GCS 3-8

***NOTE**: If the casualty has a GCS of 12 or less (moderate or severe TBI), please refer to the JTS Neurosurgery and Severe Head Injury CPG. This Biomarker CPG does not apply.*

If the casualty has no other injuries requiring evacuation, has a GCS of 13 or greater, and the TBI plasma biomarker test is not available, the MACE2 and Enclosure 3 of DoDI 6490.11 should guide initial evaluation in addition to these guidelines. (See Supporting TBI Resources for DoDI 6490.11)

This guidance and algorithm (Appendix A) expands upon the MACE2 and provides initial guidance for locations with access to the new TBI plasma biomarker test. The TBI plasma biomarker test should be used in the place of a "structural brain injury" device as listed on the MACE 2 under "red flags." However, it is important to note that this device does not provide a definitive diagnosis of a "structural brain injury" and it should be used and interpreted in accordance with the intended use statement in Appendix B. The MACE2 does not delineate which individuals should or should not undergo assessment with a structural brain injury device. This algorithm seeks to expand upon the MACE 2 to assist providers in understanding the most appropriate population for assessment with the TBI plasma biomarker.

RISK EVALUATION FOR BRAIN INJURY & INTRACRANIAL HEMORRHAGE

At locations with access to the TBI plasma biomarker test, a casualty exposed to a PCE should be stratified as high, moderate, or low risk using the Appendix A Algorithm. This is a modification of the MACE2, targeting the population most likely to benefit from the use of the TBI plasma biomarker.

HIGH RISK: DO NOT DELAY CARE FOR TBI PLASMA BIOMARKER

A subset of MACE 2 red flags suggest high risk of brain injury with intracranial hemorrhage. If any one of the following red flag signs or symptoms are present, the casualty should be referred urgently for CT scan. Do not delay evacuation to obtain TBI plasma biomarkers.

- Deteriorating levels of consciousness or a drop in post injury GCS score by 2 or greater
- Combativeness or agitated behavior
- 2 or more episodes of vomiting
- Witnessed seizure activity
- Focal neurologic deficits such as pupil asymmetry, facial weakness/asymmetry, weakness or paralysis on one side compared to the other
- Bleeding disorder or therapeutic anti-coagulation with heparin, low molecular weight heparin, warfarin, or novel oral anticoagulants (direct thrombin inhibitors and direct factor Xa inhibitors)

In addition, casualties with evidence suspicious for a penetrating brain injury, depressed skull fracture, or signs of a basilar skull fracture (e.g., raccoon eyes, battle's sign, otorrhea) should be referred urgently for CT scan.

MODERATE RISK: TEST TBI PLASMA BIOMARKERS BEFORE EVACUATION

This is the target population for TBI plasma biomarkers. Because of the significant false-positive rate, TBI plasma biomarker testing will be directed to casualties with moderate risk for intracranial hemorrhage. The goal is to allow symptomatic patients who test negative to forego CT scan and remain in place with activity restrictions (i.e. quarters, bed rest) and treatment of symptoms. There are two important caveats to this group:

1. The concussive event must have taken place within 12 hours of testing.
2. The patient should not have other injuries requiring urgent evacuation (fractures, concern for internal injuries, etc.). In this instance, testing should not hold up transport for more urgent issues, but can still be completed.

Casualties without the high risk red flag signs or symptoms described above but exhibit one or more of the following are appropriate candidates for TBI plasma biomarker testing.

- Double vision
- Increased restlessness
- < 2 episodes of vomiting
- Subjective weakness or tingling in arms or legs but no clear focal neurological deficit
- Severe, persistent, or worsening headaches
- Age >60 years
- Anti-platelet drugs (such as aspirin or ibuprofen)
- Drug/alcohol intoxication
- Post traumatic amnesia (inability to recall events for 30 or more minutes before injury)
- Worrisome mechanism of injury: high speed motor vehicle collision or rollover; fall from greater than 3ft; or presence within 50m of a blast inside or outside.

Casualties with any of these findings should be evaluated with the TBI plasma biomarker so long as the test is performed within 12 hours of the initial head injury. Then using the all the clinical details outlined on the Biomarker Data Collection Tool (Appendix D), the forward provider contacts the TBI Biomarker Consultant and the two come to a decision regarding need for head CT and priority of evacuation. When it is determined that the patient can remain in place with activity restrictions and be treated per the treatment section below, the forward provider and consultant should make a plan to communicate on the patient's progress.

LOW RISK FOR TBI: NO RISK FACTORS PRESENT

If the casualty does not have any of the risk factors described above, the provider should care for the casualty as described in the MACE2. If worsening symptoms develop more than 12 hours after the initial injury, the provider should contact the designated TBI Biomarker Consultant.

Research suggests that some casualties without MACE2 red flags undergo evacuation for head CT despite the MACE2 recommendations. If a provider wishes to obtain a head CT in individuals without the high or moderate risk signs or symptoms described above, a TBI plasma biomarker test should be

performed before referral for a head CT if the casualty is evaluated within 12 hours of injury. Consultation with the designated TBI Biomarker Consultant is strongly recommended to help determine the urgency of referral and evacuation.

LOCATIONS WITH ON-SITE HEAD CT

The TBI plasma biomarkers are a new capability both to the military and the civilian sector. As such, CPGs for the use of TBI plasma biomarkers have not yet been developed by civilian professional societies. When head CT capabilities are available on-site or evacuation is minimal risk, providers may consider performing both the TBI plasma biomarkers and head CT to gain additional experience with the TBI plasma biomarkers in clinical and operational settings. When this happens, it is imperative that a Biomarker Data Collection Tool is completed and forwarded to the consultant or TMD for the purposes of data collection on this emerging technology.

PRIMARY CONCUSSIVE BLAST

The TBI plasma biomarker was validated in civilian blunt trauma patients and it is unknown at this time how the test will perform in casualties sustaining mTBI from a primary blast wave exposure. This underscores the importance of data capture using the processes outlined in this CPG and submission of the Biomarker Data Collection Tool to JTS.

SYMPTOMATIC TREATMENT OF MILD TBI

The hallmark of treatment for service members who sustain an mTBI is relative rest and initial symptom management. Service members with mTBI should be managed in accordance with DoDI 6490.11 and the published DoD Traumatic Brain Injury Center of Excellence MACE 2 and Progressive Return to Activity Clinical Recommendation.

Many casualties with positive (elevated) results with TBI plasma biomarker will not have evidence of brain injury or intracranial hemorrhage on head CT but will have brain injury evident on Magnetic Resonance Imaging (MRI).[11] However, a TBI plasma biomarker result of “elevated” is not FDA approved for the diagnosis of mTBI and should not be used as the sole indicator of mTBI diagnosis; a clinical evaluation of the casualty is necessary to make a diagnosis of mTBI. At this time, it is not known whether casualties with positive (elevated) TBI plasma biomarkers but no evidence of injury on head CT should be treated differently from casualties with negative (not elevated) TBI plasma biomarkers. Therefore individuals with elevated biomarkers and a negative head CT should be managed as individuals with mTBI as per DoD guidelines cited in the preceding paragraph.

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

Casualties exposed to a potentially concussive event.

INTENT (EXPECTED OUTCOMES)

1. Documented GCS, neurologic exams, MACE2 and symptoms for each service member exposed to a potentially concussive event.
2. TBI Plasma Biomarker performed on moderate risk patients within 12 hours of injury.
3. TBI Biomarker Consultant is informed on all positive and negative TBI Plasma Biomarker tests, resulting in completion of the Biomarker Data Collection Tool (Appendix D).
4. Biomarker Data Collection Tool is submitted/emailed to JTS: dha.jbsa.healthcare-ops.list.tbi-biomarker@health.mil

PERFORMANCE/ADHERENCE MEASURES

1. MACE2 exams documented on all Service Members diagnosed with mTBI
2. Documented results of the TBI plasma biomarker in the patient's medical record

DATA SOURCES

- Patient Record
- Department of Defense Trauma Registry

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Chief and the JTS PI Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local level with this CPG.

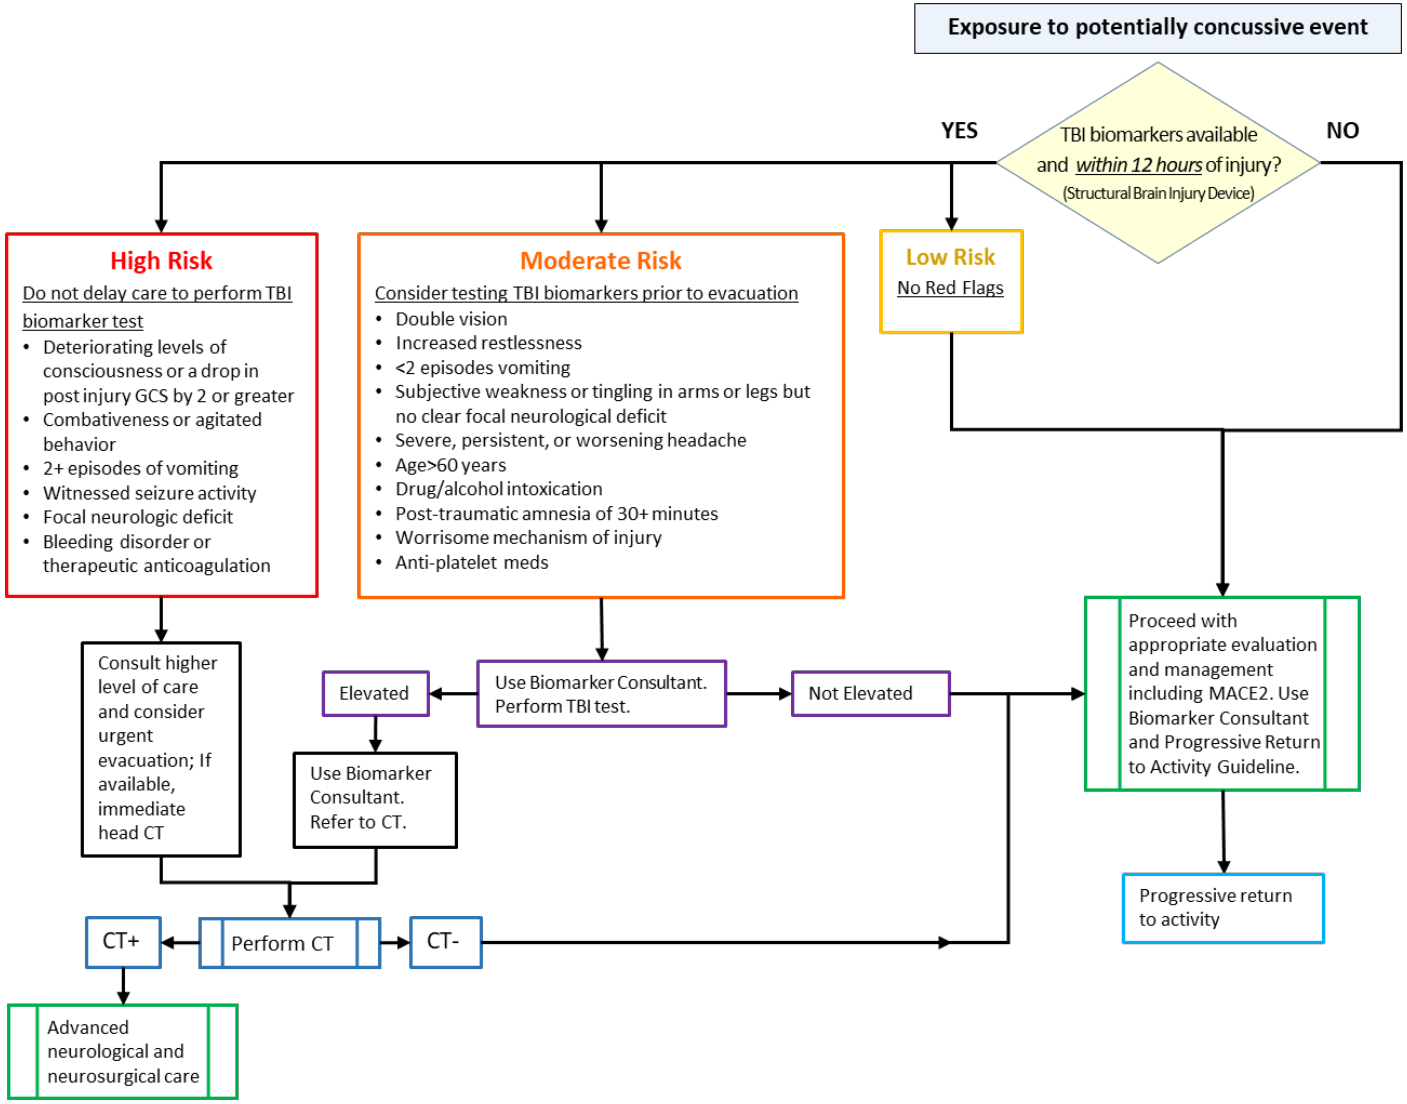
APPENDIX A: CLINICAL ALGORITHM FOR TBI BLOOD BIOMARKERS USE

Clinical Algorithm for Initial Management of a Potentially Concussive Event using the TBI Blood Biomarkers



APPENDIX B: DETAILED INFORMATION ON THE TBI PLASMA BIOMARKER

***NOTE**: Information summarized from Abbott Point of Care Inc., 2021, 510(k) Summary: i-STAT TBI Plasma Cartridge with the i-STAT Alinity System (K201778; Approved 8JAN2021). https://www.accessdata.fda.gov/cdrh_docs/pdf20/K201778.pdf.*

Capability Name: Analyzer, Traumatic Brain Injury System

Device Name: i-STAT TBI Plasma Cartridge with the i-STAT Alinity System

Device and Assay Description:

- Semi-quantitative multiplex immunoassay in ethylenediaminetetraacetic acid (EDTA) anticoagulated plasma for:
  - Glial fibrillary acidic protein (GFAP)
  - Ubiquitin carboxyl-terminal hydrolase-L1 (UCH-L1)
- Cartridge can only be used on the i-STAT Alinity.
- Will give an error reading if used on i-STAT 1.
- To separate plasma, blood requires processing in clinical laboratory settings with centrifuge capability.
- Cartridges require refrigerated storage; calibration/verification and control fluids require freezer for storage.
- Cannot be used as a point of care test in near patient settings; this may be possible for future products.

Assay Reference Range:

Range derived from n=225 apparently healthy individuals with no history of neurological disease:

- GFAP: Mean 19 pg/mL; Median 15 pg/mL; Reference Interval 2-51pg/mL (2.5th -97.5th percentile)
- UCH-L1: Mean 81 pg/mL; Median 71 pg/mL; Reference Interval 21-204 pg/mL (2.5th -97.5th percentile)

Assay Cut-Off Values and Results:

- Elevated: An elevated result is given if either GFAP OR UCH-L1 is elevated
  - GFAP cut-off: 30 pg/mL
  - UCH-L1 cut-off: 360 pg/mL
- Not elevated: A not elevated result is given if GFAP AND UCH-L1 are below the cut-off
- Not reportable: No result is given if valid results are below the cut-off AND one or more results are not reportable

Assay Performance

There were two studies performed as part of the U.S. Food and Drug Administration (FDA) licensure process.

***Study #1**: This study was conducted on stored plasma samples and demonstrated performance comparable to the Banyan Biomarkers assay with:*

- sensitivity of 95.8% [95% Confidence Interval (CI) 90.6%, 98.2%],
- negative predictive value of 99.3% [95%CI 98.5%, 99.7%], and
- specificity of 40.4% [95%CI 38.2%, 42.7%].

(See Appendix C for additional details.)

***Study #2**: This study was conducted on fresh plasma samples and demonstrated comparable sensitivity but lower specificity.*

- sensitivity of 100.0 [95% CI 88.3%, 100.0%],
- specificity of 23.7% [95%CI 14.7%, 36.0%].

(See Appendix C for additional details.)

Intended Use Statement

The i-STAT TBI Plasma test is a panel of in vitro diagnostic immunoassays for the quantitative measurements of GFAP and UCH-L1 in plasma and a semi quantitative interpretation of test results derived from these measurements, using the i-STAT Alinity Instrument. The interpretation of test results is used in conjunction with other clinical information to aid in the evaluation of patients, 18 years of age or older, presenting with suspected mild traumatic brain injury (Glasgow Coma Scale score 13-15) within 12 hours of injury, to assist in determining the need for a CT scan of the head. A "Not elevated" test interpretation is associated with the absence of acute traumatic intracranial lesions visualized on a head CT scan. The test is to be used with plasma prepared from EDTA anticoagulated specimens in clinical laboratory settings by a healthcare professional. The i-STAT TBI Plasma test is not intended to be used in point of care settings.

APPENDIX C: SUMMARY OF RESEARCH

Overall Summary of Evidence

Two studies were conducted in support of the FDA licensure request.[1] The first study used frozen plasma samples obtained from the study conducted in support of the Banyan Biomarkers TBI Assay.[2] This study (n=1901) demonstrated comparable performance to the Banyan Biomarkers assay with a sensitivity of 95.8%, negative predictive value of 99.3%, and specificity of 40.4% [95%CI 38.2%, 42.7%]. There were n=5 false negative test results; none of these were abnormalities requiring surgical intervention.[2]

The second study used a small sample of fresh plasma samples (n=88) obtained from a small subset of patients a study of TBI at Level 1 Trauma Centers who had head CT performed. In this sample the sensitivity and negative predictive value were 100%, but the specificity was lower - 23.7%. The reason for the lower specificity in this population is not clear but may have been due to the small sample size or due to differences in the study population. For example, only 6% of the population in the first study had findings on head CT as compared to this study where 33% had findings on head CT. The positive predictive values for the two studies were comparable after adjustment for the prevalence of positive head CT.

While the specificity of the assay is low to moderate for brain injury and hemorrhage visible on CT, additional research suggests that many individuals with elevated Glial Fibrillary Acidic Protein using a prototype of the assay have evidence of brain injury on MRI.[3] It is important to note the assay is not FDA approved for this purpose.[1]

Summary of Study #1

Stored frozen plasma samples were obtained from Bazarian, et al study used for approval of Banyan Biomarkers TBI assay, an early version of this assay.[1,2]

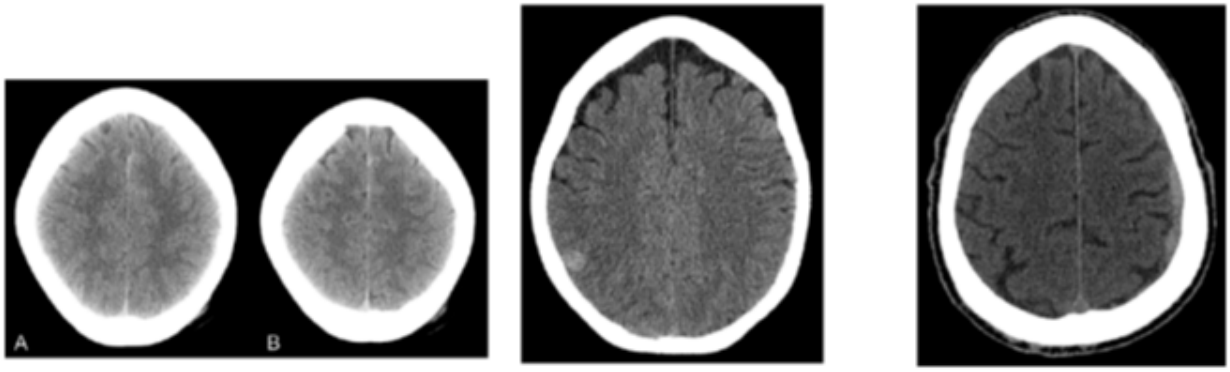
- **Inclusion/Exclusion Criteria**: Adults ≥18 years, presenting to Emergency Department with non-penetrating TBI and GCS 13-15, where the referring provider felt a head CT was indicated, with blood test within 12 hours of injury at 22 sites in the U.S. and Europe
- **The study population** (n=1901) had a median age of 49.0 years and ranged from 18 to 98 years. Over half (56.6%) were male and 70.6% were white and 26.2% were African American.
- Nearly all had a GCS of 15 (94.1%) and around half had Loss of Consciousness (42.2%), Alteration of Consciousness (56.3%), or visible trauma above the clavicle (63.3%). Around one-third reported post-traumatic amnesia (33.0%).
- The median time between injury and blood draw was 3.2 hours with a range of 0.3 to 11.9 hours.

Table 1. Clinical Performance

Clinical Performance			
i-STAT TBI Plasma Test Interpretation	Adjudicated CT Scan Result		Total
	Positive	Negative	
Elevated	115	1061	1176
Not Elevated	5	720	725
Total	120	1781	1901
Clinical Performance Parameters	N=1901	95% Confidence Interval	
Clinical Sensitivity	95.8%	90.6%, 98.2%	
Clinical Specificity	40.4%	38.2%, 42.7%	
Negative Predictive Value (NPV)	99.3%	98.5%, 99.7%	
Positive Predictive Value (PPV)	9.8%	9.2%, 10.2%	
Likelihood Ratio Negative (LRN)	0.10	0.04, 0.23	
Likelihood Ratio Positive (LRP)	1.61	1.15, 1.69	

- There were five individuals with false negative results (i.e. not elevated biomarker result and findings on head CT). None of these individuals required surgical intervention. Findings included a small sub-arachnoid hemorrhage, a small subdural hemorrhage and a venous angioma thought to be a congenital anomaly. See Figure 1 for 3 of the 5 head CT scans from false negative subjects.

Figure 1. Head CT Scans from false negative subjects



Legend: Left (subject 1) – Two non-contrast CT images (A + B) show focal subarachnoid hemorrhage in the anterior, paramedian frontal sulci. Middle (subject 2) – Non-contrast CT image shows a focal area of hyperdensity in the posterior right parietal lobe. On lower slices (not shown), there is a suggestion of some lower attenuation edema which marginates the contusion. Right (subject 3) – Non-contrast CT image shows subdural hemorrhage along the left lateral hemisphere, overlying the frontal and parietal lobes with minimal local mass effect on the brain parenchyma.

Summary of Study #2

Fresh plasma samples were obtained from four clinical sites of the *Transforming Research and Clinical Knowledge in Traumatic Brain Injury (TRACK-TBI) study* in the United States.[1,3]

- **Inclusion/Exclusion Criteria**: Adults ≥18 years, presenting to Emergency Department with GCS 13-15, who had a head CT performed at 4 sites in the U.S.
- **The study population** (n=88) had a median age of 42.5 years and ranged from 18 to 85 years. Nearly three-quarters (71.2%) were male.
- Most had a GCS of 15 (81.8%) and over half had loss of consciousness (68.2%), presence of confusion (67.0%), or post-traumatic amnesia (68.2%).
- The median time between injury and blood draw was 4.3 hours with a range of 2.0 to 11.8 hours.

Table 2. Clinical Performance – Supplemental Fresh Specimen Study

Clinical Performance – Supplemental Fresh Specimen Study			
i-STAT TBI Plasma Test Interpretation	Adjudicated CT Scan Result		Total
	Positive	Negative	
Elevated	29	45	74
Not Elevated	0	14	14
Total	29	59	88
Clinical Performance Parameters	**N=88**	**95% Confidence Interval**	
Clinical Sensitivity	100.0%	88.3%, 100.0%	
Clinical Specificity	23.7%	14.7%, 36.0%	
Negative Predictive Value (NPV)*	100.0%	80.2%, 100.0%	
Positive Predictive Value (PPV)*	39.2%	35.9%, 43.4%	
Likelihood Ratio Negative (LRN)	0.00	0.00, 0.50	
Likelihood Ratio Positive (LRP)	1.31	1.14, 1.56	

*Legend: *NPV and PPV estimated at 33.0% prevalence of CT scan positive rate for suspected mild TBI subjects. Adjusted NPV and PPV at 6% prevalence (to be comparable to the pivotal study) are 100.0% (95% CI: 96.9%, 100.0%) and 7.7% (95% CI: 6.8%, 9.1), respectively.*

Summary of GFAP/MRI Study

Yue JK, Yuh EL, Korley FK, et al. Association between plasma GFAP concentrations and MRI abnormalities in patients with CT-negative traumatic brain injury in the TRACK-TBI cohort: a prospective multicentre study. Lancet Neurol. 2019;18(10): 953-961. https://doi.org/10.1016/s1474-4422(19)30282-0

The study enrolled adults with GCS 13-15 between 2014-2018 at 18 participating Level 1 U.S. trauma centers who presented within 24 hours of injury and had a head CT as well as an MRI within 7-18 days post injury.[1,3]

- Of 1375 individuals enrolled in TRACK-TBI study, 794 had negative head CT and a GCS of 13-15 of whom 450 had an MRI scan performed within 7-18 days. Of these, 27% had positive MRI.
- Individuals with positive head CT had the highest GFAP levels (Median 786.0 pg/mL); followed by those with negative head CT and positive MRI (Median 414.4 pg/mL); followed by those with negative head CT and negative MRI (Median 74.0 pg/mL). Of note, healthy (Median 8.0 pg/mL) and orthopedic trauma (Median 13.1 pg/mL) controls had significantly lower GFAP levels (Table 3/Figure 2).
- From a pathophysiologic perspective, elevated GFAP levels were noted in traumatic axonal injury, diffuse axonal injury, extra-axial and mixed lesions (See Figure 2).
- The sensitivity and specificity of GFAP levels for positive MRI is listed in Table 4. Of note, GFAP levels greater than 282.70 pg/mL has a specificity of 80.3% for positive MRI.

Table 3. Plasma GFAP concentrations by imaging modality and findings

Plasma GFAP concentrations by imaging modality and findings					
	No of patients	Plasma GFAP concentrations (pg/mL)			
		Mean (SD)	Median (25-75th percentile)	Range	P value
Positive CT	199	1400.9 (1598.6)	786.0 (357.0-1863.3)	0-9409.7	<0.0001*
Negative CT	450	308.0 (530.5)	110.3 (22.7-352.3)	0-4095.1	..
Negative CT & positive MRI	120	692.2 (827.6)	414.4 (139.3-813.4)	5.2-4095.1	<0.00001†
Negative CT & negative MRI	330	168.3 (250.9)	74.0 (17.5-214.4)	0-1864.5	..
Orthopaedic trauma controls	122	23.7 (37.2)	13.1 (6.9-20.0)	0-216.8	<0.0001‡∫
Healthy controls	209	11.0 (12.7)	8.0 (3.0-14.0)	0-98.0	<0.0001‡∫

*GFAP=glial fibrillary acidic protein. P values were calculated from the Wilcoxon rank sum test for the comparisons, which compares the distributions of the two groups. *Compared with patients with negative CT. †Compared with patients with negative CT and negative MRI findings. ‡Compared with patients with negative CT and positive MRI findings. ∫ Compared with patients with negative CT and negative MRI findings.*

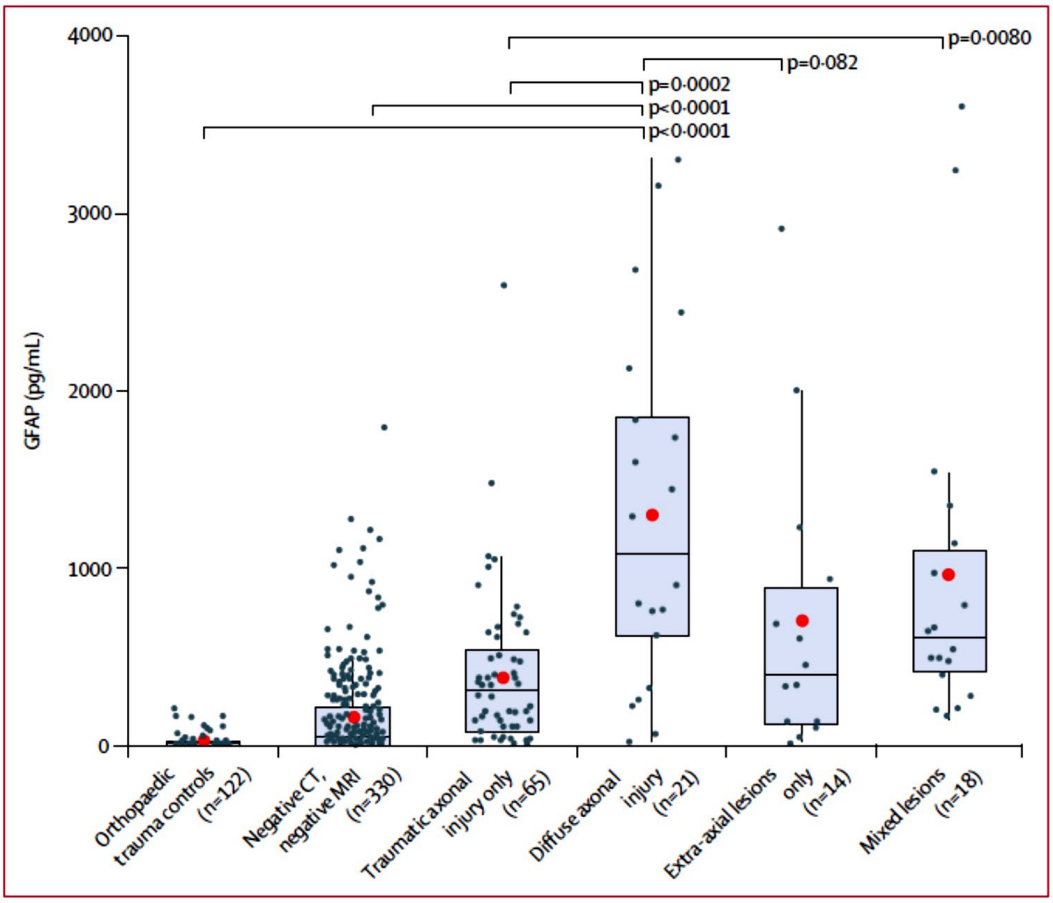
Figure 2. GFAP concentration by MRI pathology



The red dot signifies mean plasma GFAP concentration while boxplots provide range, median, and 25-75th percentiles. Individual dot values are plotted for reference. The Dunn Kruskal-Wallis test for comparisons among different MRI lesion types with a Benjamin-Hochberg correction for multiple comparisons[23] showed that GFAP concentrations are significantly higher in patients with isolated diffuse axonal injury than in those with isolated traumatic axonal injury. Separate Wilcoxon rank sum tests also showed significantly higher GFAP concentrations in patients with isolated diffuse axonal injury than in patients with negative CT and negative MRI findings, and orthopaedic trauma controls. P values are displayed for relevant comparisons. Two patients with isolated intracerebral contusions (GFAP 14.9 pg/mL, 285 4 pg/mL were not included as boxplot. GFAP=glial fibrillary acidic protein.

Table 4. Cutoff concentrations of plasma GFAP to predict MRI-positive versus MRI-negative findings in patients with negative CT

	Sensitivity	Specificity	NPV	PPV
4.40 pg/mL	1.000 (1.000-1.000)	0.024 (0.009-0.042)	1.000 (1.000-1.000)	0.271 (0.268-0275)
12.95 pg/mL	0.958 (0.925-0.992)	0.188 (0.148-0.230)	0.925 (0.863-0.981)	0.300 (0.287-0.313)
25.15 pg/mL	0.908 (0.850-0.958)	0.333 (0.288-0.388)	0.910 (0.861-0.957)	0.332 (0.312-0.354)
71.95 pg/mL	0.825 (0.750-0.892)	0.494 (0.442-0.549)	0.888 (0.845-0.924)	0.373 (0.344-0.407)
282.70 pg/mL	0.642 (0.558-0.733)	0.803 (0.758-0.842)	0.861 (0.832-0.890)	0.543 (0.482-0.603)
848.75 pg/mL	0.233 (0.158-0.308)	0.964 (0.942-0.982)	0.775 (0.760-0.793)	0.698 (0.555-0.842)

The k-fold cross validation method was used to select the optimal cutoffs for predicting MRI-positive versus MRI-negative findings in patients with negative CT based on the criteria of adjusted NPV above the level of 0·96, 0·94, 0·92, and 0·90, 0·85, and 0·80, in accordance to data standards for clinical laboratory assays set by the manufacturer. The prevalence of positive MRI scans among patients with negative CT scans was estimated to be 0·27 on the basis of the sample rate to calculate the adjusted NPV.1000 bootstraps were conducted to determine the optimal cutoffs using the median from each run. The optimal cutoff thresholds were than applied to the full data to calculate the corresponding sensitivity, specificity, NPV, and PPV. GFAP=glial fibrillary acidic protein. NPV=negative predictive value. PPV=positive predictive value.

APPENDIX E: INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Vascular Injury (CPG ID: 46)

The CPG provides guidance on the diagnosis, treatment and surgical management of vascular injuries sustained by combat casualties.

BACKGROUND

The treatment of vascular injuries in combat casualties can be a challenging endeavor in a resource limited environment and requires not only technical expertise on the part of the operating surgeon, but solid judgment on when to perform temporizing maneuvers versus definitive repairs. Surgeons at all Role 2 and 3 facilities need to be intimately familiar with the use of vascular shuts as a means to stabilize a critically wounded casualty and then move them along the continuum of care. With the evolution of global conflict, military surgeons at Role 2 facilities may be faced with potential obstacles to timely patient evacuation, or may be tasked to operate in an environment without an available Role 3 facility. They must also therefore be competent in the definitive surgical management of certain common and life or limb-threatening vascular injuries.

EPIDEMIOLOGY OF VASCULAR INJURY

The rate of vascular injury in modern combat is five times that reported in previous wars and one in five (20%) battle injuries (non-return to duty) are classified as hemorrhage control not otherwise specified suggesting the presence of significant bleeding. Using codes for specific blood vessel injuries or repairs, the rate of vascular injury is 12% in OIF and OEF, which is higher than the 1-3% reported in WWII, Korea and Vietnam.[1] Extremity vessels account for 70-80% of vascular injuries while 10-15% are in the cervical region and 5-10% in the torso.1-3 The widespread training and use of tourniquets in the modern battle field is likely one of the major reasons for the increase in vascular injuries seen. Casualties that would have died in the field in prior conflicts are now reaching medical care.

ECHELONS OF CARE AND VASCULAR INJURY

Each echelon has unique approaches to the management of vascular injury: [3]

- **Role 1** – Hemorrhage control (direct pressure, tourniquet or topical hemostatic agent) or other life-saving interventions and initiation of evacuation.
- **Role 2** – Operations at forward operating locations are abbreviated (<1 hour), however intervention on extremity vascular injury is important and may make the difference in meaningful limb salvage. Primary amputation or ligation is also an acceptable damage control technique when other life-threatening injuries are present or the patient is in extremis. However if limb salvage is to be attempted, initiation of basic maneuvers including removal of tourniquet, exploration and control of the vascular injury, removal of clot (thrombectomy) and administration of heparinized saline through the inflow and outflow vessels are recommended. Restoration of flow can then be established using a temporary vascular shunt followed by fasciotomy and initiation of medical evacuation. Temporary shunt placement for the initial management of proximal extremity vascular injury is associated with very high rates of successful limb salvage, and consistent shunt patency has been demonstrated for periods up to 12 hours.[4,5] However, experience with shunt utilization without systemic anticoagulation for more protracted periods is limited, and the risk of shunt thrombosis is markedly increased when used beyond 12 hours.[6,7] If a significant delay before definitive vascular management is anticipated, Role 2 surgeons should consider definitive management of the injury with repair/reconstruction or ligation, depending on the patient's stability and the experience level of the surgeon.
- **Role 3** – Removal of tourniquet(s) and any temporary vascular shunts placed at forward locations followed by definitive vascular repair using saphenous vein should be performed at this echelon. Synthetic PTFE conduit can be used in the absence of appropriate autologous vein. During aeromedical evacuation the extremity will be difficult to examine, therefore Role 3 surgeons must assure adequacy of limb perfusion, fasciotomy and wound debridement. Primary amputation or ligation is also an

acceptable damage control technique at this echelon of care when other life-threatening injuries are present or the patient is in extremis.

- **Overseas Role 4** – Surveillance of vascular repair including a close assessment of soft tissue wounds and adequacy of tissue coverage in the operating room prior to continuing MEDEVAC.
- **Continental United States (CONUS) Role 5**– Surveillance of vascular repair with duplex or CTA8 as well as assessment of soft tissue wounds and adequacy of tissue coverage is performed at this echelon. Angiography has particular utility in the identification of more subtle vascular injuries (e.g., traumatic pseudoaneurysm, arteriovenous fistula) following blast injury.[9] In some instances, revision of at-risk repairs identified as having a stenosis or inadequate tissue coverage leaving them prone to infection and blowout is necessary.[10] Finally, delayed revascularization of viable but poorly perfused extremities in which ligation was chosen as the initial method of management can be accomplished at this echelon.

DIAGNOSIS OF VASCULAR INJURY

1. **Hard signs such as hemorrhage, obvious ischemia, palpable thrill or expanding** hematoma require immediate management in the operating room, generally with exploration of the injury site with wide exposure to enable vascular control. Ischemia in this situation is defined as the absence of Doppler signal in the extremity on multiple attempts over time, including after initiation of resuscitation and warming. When hard signs of injury are present, there is limited need for other diagnostic tests (i.e. CTA or angiography) which take extra time and may provide findings which cloud decision making.[3,11,12]

2. **Soft signs such as history of significant hemorrhage, injury proximity to major vessels (fracture pattern, dislocation, penetrating wound or blast injury), bruising or hematoma** or question regarding the presence or absence of a palpable pulse require another diagnostic test. This additional test is commonly the continuous wave Doppler with calculation of the injured extremity index for traumatized limbs if possible and CTA or angiography for questionable torso and/or extremity vascular injuries where available.

3. **The injured extremity index** is similar to the ankle-brachial index and is calculated using a manual blood pressure cuff and a continuous wave Doppler. The first step is to determine the pressure at which the arterial Doppler signal returns in the injured extremity as the cuff is deflated, this is the numerator in the equation. Next the cuff and Doppler are moved to the uninjured extremity, ideally an uninjured upper extremity, and again the pressure at which the arterial Doppler signal returns as the cuff is deflated is recorded as the denominator in the ratio. An injured extremity index greater than 0.90 is normal and has a high specificity for excluding major extremity vascular injury.[13]

4. **Angiography has limited utility in the diagnosis of wartime extremity vascular injury** which is, in part, related to the availability and quality of imaging technology in austere environments. Additionally, extremity vasoconstriction associated with shock and hypothermia in the young injured patient may lead to confusing or false positive findings on angiography. Angiography has its greatest utility in the setting of multiple penetrating wounds at various levels of the same extremity and when performed should be done via a cut down on the femoral artery using a 19-21 gauge butterfly needle to inject contrast. In most instances it is acceptable to forego angiography and use an incision to expose the segment in question with the plan to ligate, shunt or repair the vascular injury.

5. **Computed Tomography-Angiography (CTA)** is increasingly available in a mature theater of war and has its greatest utility in the diagnosis and triage of torso and neck wounds. Reports of CTA for evaluation of extremity vascular injury now exist; however this modality should be viewed as an adjunct, as its full utility has yet to be determined. Specifically, CTA for head and neck wounds demonstrates a sensitivity

of 80%.[14,15] Furthermore, this modality takes additional time, IV contrast and technical experience in order to provide accurate and meaningful images.

GENERAL PRINCIPLES OF VASCULAR INJURY MANAGEMENT

Most deploying non-vascular or non-cardiothoracic surgeons will have limited recent experience in vascular surgery. Prior to deployment, training for surgeons should emphasize the basic principles of vascular trauma management, including adequate exposure, proximal and distal control, vessel debridement to viable tissue, the creation of a tension-free anastomosis, repair or shunt, and adequate coverage with viable tissue. The most challenging aspect in the management of a wartime vascular injury is generally related to vascular exposure. As most of these injuries involve previously normal blood vessels, vessel suturing and shunt placement are usually a relatively straightforward technical exercise. However, in the face of tissue destruction, hematoma, distorted anatomic landmarks, and the potential absence of a palpable pulse, the identification and adequate exposure of a wartime vascular injury can be a challenge for even an experienced surgeon. While the deploying surgeon will find the techniques and "pearls" in Appendix A and Appendix B extremely valuable for pre-deployment review and as a reference during deployment, surgeons should also maximize opportunities to review anatomic exposures in cadaveric, simulation, and video settings prior to deployment. Furthermore, an atlas that covers vascular surgery and exposures should be at the immediate ready for every surgeon on a combat deployment.

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

- All patients with penetrating injury to an extremity proximal to knee/elbow with AIS ≥ 2 or diagnosis of posterior knee dislocation.
- All patients diagnosed with injury to major artery or vein (subclavian, axillary, carotid, brachial, common femoral, superficial femoral, popliteal, common iliac, external iliac, internal iliac, aorta, vena cava, portal vein, hepatic artery, mesenteric artery, renal artery).

INTENT (EXPECTED OUTCOMES)

1. All patients with penetrating injury to an extremity proximal to knee/elbow with AIS ≥ 2 or diagnosis of posterior knee dislocation have injured extremity index documented.
2. All patients with penetrating injury to an extremity proximal to knee/elbow with AIS ≥ 2 or diagnosis of posterior knee dislocation have neuro and vascular exam documented.
3. All patients diagnosed with injury to major artery or vein undergo revascularization (shunt or repair) or ligation at the first surgical capability (or valid explanation for delay documented) prior to transfer to next level of care.
4. All patients diagnosed with injury to major artery or vein who undergo reperfusion (shunt or repair) have the procedure within 4 hours of injury.

PERFORMANCE/ADHERENCE METRICS

1. Number and percentage of patients in the population of interest who have injured extremity index documented.
2. Number and percentage of patients in the population of interest who have neuro and vascular exam documented.

3. Number and percentage of patients in population of interest who undergo revascularization (shunt, repair, ligation) prior to transfer to next level of care.

4. Number and percentage of patients in population of interest who injury undergo reperfusion (shunt or repair) or ligation within 4 hours of injury.

DATA SOURCE

- Patient Record
- Department of Defense Trauma Registry (DoDTR)

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the Joint Trauma System (JTS) Chief and the JTS Performance Improvement Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local echelon with this CPG

APPENDIX A: EXTREMITY VASCULAR INJURY

NOTE: *See Figure 1. Algorithm for Extremity Vascular Injury*

UPPER EXTREMITY

Subclavian Artery

- Recommendations: Repair
- Utility of temporary shunt: Low
- Method/ Conduit: Interposition graft /6-8mm ePTFE or Dacron

Pearls

- Proximal right subclavian is approached through median sternotomy and the proximal left subclavian through a high left anterolateral thoracotomy
- The supraclavicular approach is through the clavicular head of sternocleidomastoid muscle and scalene fat pad with retraction of phrenic nerve and division of the anterior scalene muscle
- Place gentle role under shoulders and extend head away from side of injury

Avoid injury to phrenic nerve, brachial plexus and vertebral arteries. The proximal left subclavian artery is approached using a high (3rd intercostal space) anterolateral thoracotomy and the innominate and proximal right subclavian artery through a median sternotomy and supraclavicular incision. The innominate vein can be ligated and divided to facilitate exposure to the innominate artery. Alternatively, the mid and distal subclavian arteries on both sides can be exposed through a supraclavicular incision or combined supraclavicular/infraclavicular incisions. There is no requirement to obtain proximal vascular control within the surgical field of injury; using separate incisions through non-traumatized tissues can expedite rapid vascular control. When approaching this injury the operator should err on the side of ample proximal exposure and if necessary, can resect the clavicular head. In an unstable patient it is recommended that initial proximal control be obtained via thoracotomy as this will allow for more rapid control than use of the supraclavicular approach. Because of the technical challenges with exposure, the utility of temporary vascular shunts in this injury pattern is limited. Most often interposition graft using 6-8 mm ePTFE or Dacron is required for subclavian artery repair, being mindful of the vertebral artery and the phrenic nerve. If endovascular capability is available, balloon occlusion of the proximal subclavian artery can be a useful adjunct, and repair with a covered stent can be considered. [2,6]

Axillary Artery

- Recommendations: Repair
- Utility of temporary shunt: High
- Method/ Conduit: Interposition graft/ reversed saphenous vein

Pearls

- Supra- and infraclavicular incisions allows proximal control and distal exposure.
- Prep axilla, arm and hand of upper extremity into operative field.
- Avoid brachial plexus which will be deep or lateral to axillary artery.

Control of the proximal axillary artery is best accomplished through a supraclavicular incision, although the artery itself is exposed through an infraclavicular incision extending into the axilla. The infraclavicular exposure

includes division of the clavipectoral fascia, and the blunt separation of the fibers of the pectoralis major muscle for entire the length of the wound. The axillary vein is the first structure to be encountered in the axillary sheath. The axillary artery lies superior and deep to the vein, mobilization and caudal retraction of the axillary vein will expose the first segment of the axillary artery. The first segment of the axillary artery is then visible coursing under the pectoralis minor muscle which can be retracted laterally or divided. It is important when exposing the artery to have the arm and hand prepped in the operative field and extended out onto an arm board. Repair of the axillary artery most commonly involves an interposition graft using reversed saphenous vein.

Brachial Artery

- Recommendations: Repair
- Utility of temporary shunt: High
- Method/ Conduit: Interposition graft/ reversed saphenous vein

Pearls

- Medial approach; adjacent to the median nerve in brachial sheath in bicep/triceps groove.
- Elastic artery with redundancy; flex arm slightly for interposition grafts to avoid kinking.
- Depending upon damage to collaterals, distal ligation (below profunda brachial or deep brachial artery) may be tolerated.

The brachial artery with the median nerve rests in the brachial sheath and is exposed through a medial incision in the upper arm in the groove between the bicep and triceps. The median nerve is the most superficial structure encountered upon entering the brachial sheath. The ulnar nerve runs posterior to the artery which is surrounded by paired deep brachial veins. A common anatomic variant is for there to be a high bifurcation of the brachial artery in the upper third of the arm. Repair is most commonly accomplished using a reversed saphenous vein interposition graft. Although it may be possible to ligate the brachial artery below the origin of the deep (profunda) brachial artery and maintain a viable arm and hand, this proposition is based on intact collateral circulation. Unfortunately collaterals from the shoulder and deep brachial artery are often damaged in the setting of penetrating blast wounds and therefore maintenance of flow through the brachial artery with a temporary shunt or vascular repair is advised. Ligation or primary amputation is an acceptable damage control maneuver if there is not time for shunting or the patient is in extremis.

Radial/Ulnar Arteries

- Recommendations: Selective (repair some but not all)
- Utility of temporary shunt: Low
- Method/ Conduit: Ligation or interposition graft/ reversed saphenous vein

Pearls

- The presence of an arterial Doppler signal in the hand obviates the need for artery repair.
- Repair with saphenous vein in instances where the absence of an arterial signal persists.

Most often the hand has a dual arterial supply and therefore can tolerate ligation of either the radial or ulnar artery. As such, repair or reconstruction of an injury at this level is rare. Perfusion to the hand should be assessed with Doppler before and after occlusion or ligation, and if the absence of a signal persists, reconstruction with reversed saphenous vein should be performed. Given the relative small muscle mass of the

hand and the degree of collateral circulation, ligation is most often tolerated understanding that if ischemia persists, evaluation and revascularization can be performed at a CONUS facility days or weeks later.

LOWER EXTREMITY

Common Femoral Artery

- Recommendations: Repair
- Utility of temporary shunt: High
- Method/ Conduit: Interposition graft/ saphenous vein or 6-8mm prosthetic

Pearls

- Expose abdominal wall and artery coursing under inguinal ligament for proximal control.
- External iliac artery can be controlled through proximal groin or low abdominal incision.
- Coverage with tissue (femoral sheath), sartorius muscle or rectus flap.

Injury to the common femoral artery is often fatal as hemorrhage control in the field is difficult. Exposure is obtained through a single longitudinal incision above the artery (2-3 cm lateral to the pubic tubercle) exposing the artery at the inguinal ligament. A key point in exposing the femoral artery is placing the incision proximal enough so that the abdominal wall and inguinal ligament can be identified first in a consistent and familiar location. Alternatively, proximal control can be obtained in the retroperitoneum (i.e. external iliac) through the proximal extension of this groin incision or by using a limited transverse incision in the lower abdomen. After a transverse-oblique skin incision, the external and internal oblique aponeuroses are divided and the lateral fibers of the internal oblique separated. The transversus muscle and transversalis fascia are opened allowing entrance into the retroperitoneum, and the peritoneum is reflected cephalad, exposing the internal iliac vessels along the medial border of the psoas muscle. Common femoral artery injuries are most commonly reconstructed using reversed saphenous vein, although e-PTFE or Dacron can be used if there is too great of a size mismatch. Placement of a prosthetic graft is acceptable if there is minimal to no contamination and there is adequate coverage, at a Role 2 facility placing a shunt prior to transfer to a higher level of care is preferable to reconstruction with a prosthetic graft. Every attempt should be made to maintain flow into the profunda femoris artery, although the feasibility of this will depend upon the pattern of injury and the comfort level the surgeon to perform a more complicated reconstruction. Coverage of vascular reconstructions in the groin is challenging and the focus of Role 3-4 care and may consist of local viable tissue, the sartorius muscle or other options such as a rectus abdominis transfer flap. [2,17]

Profunda Femorus Artery

- Recommendations: Repair if possible
- Utility of temporary shunt: Low
- Method/ Conduit: Ligation or interposition graft/ saphenous vein

Pearls

- Exposure of proximal profunda is the same (distal extension) of the common femoral.
- If superficial femoral artery is injured, repair of profunda is necessary to heal amputations.
- If superficial femoral is patent, ligation of mid to distal profunda injury is acceptable.

Exposure of the proximal profunda femoris artery is obtained through a longitudinal incision used to expose the common femoral artery. Mid- and distal segments are exposed through a vertical incision made parallel to the

lateral border of the Sartorius muscle more lateral incision on the upper thigh, lateral to the proximal sartorius muscle. The sartorius is retracted medially and the rectus femoris is retracted laterally to expose the mid- and distal segments. Proximal profunda injuries should be repaired with reversed saphenous vein interposition graft. This is especially important if there is question about the integrity of the superficial femoral or popliteal vessels. In this setting flow through the profunda is most important to allow healing of subsequent lower extremity amputations. If patency of the superficial femoral artery can be confirmed, ligation of mid and distal profunda femoris injuries is acceptable as they lie deep in the thigh musculature and are not required for leg viability. [17]

Superficial Femoral Artery

- Recommendations: Repair
- Utility of temporary shunt: High
- Method/ Conduit: Interposition graft/ reversed saphenous vein

Pearls

- Medial incision with "bump" under calf, surgeon seated, OR lights over shoulder.
- Exposure of the proximal 1/3 posterior to the sartorius and distal 1/3 anterior to the Sartorius.
- Be wary of adjacent vein and geniculate branches of distal superficial femoral artery (Hunter's canal).

Exposure is performed through a medial thigh incision and the adductors of the leg (i.e. adductor magnus). Exposure is facilitated by placing a lift or "bump" below the knee which allows the femoral artery, sartorius and adductors to be suspended improving separation. Entry into the fascia of the lower thigh (distal superficial femoral artery) should be performed at the upper anterior margin of the sartorius which should be reflected down or posteriorly. Exposure is facilitated with the surgeon seated looking across to the dissection field with lights positioned directly over his or her shoulder if they do not have a headlight available.

When exposing the superficial femoral artery, it is important to recognize the femoral vein which is in close proximity, if not adherent, to the artery. At the distal extent of the artery as it exits the adductor (Hunter's) canal, there are large geniculate side branches which should be preserved or at least not injured which causes hemorrhage. Repair of superficial femoral artery injury is best performed by reversed saphenous vein interposition graft from the uninjured leg.[17]

Popliteal Artery

- Recommendations: Repair
- Utility of temporary shunt: High
- Method/ Conduit: Reversed saphenous vein

Pearls

- Medial incision with "bump" under calf for above knee and under thigh for below knee.
- Henley popliteal retractor with removable, varied depth side blades is valuable.
- Distal exposure by division of gastrocnemius and soleus from tibia allowing dissection to anterior tibial origin (coursing away from dissection plane) and tibial-peroneal trunk.

Vascular injuries in the popliteal space are exposed through a medial incision with the surgeon seated and lights over his or her shoulder. The dissection is extended from above to below the knee and is facilitated by a lift or "bump" under the calf of the leg with the knee flexed. When exposing below the knee, this bump is placed

under the thigh. Natural dissection planes exist in exposing the above knee popliteal artery (i.e. popliteal space) with the exception of the need to divide the fibers of the adductor magnus which envelop the distal superficial femoral artery (Hunter's canal). Similarly, a natural dissection plane exists into the popliteal space from below the knee, but added exposure should be accomplished by division of the gastrocnemius and soleus muscle fibers from the medial tibial condyle to allow a lengthy exposure of the below knee popliteal artery to the takeoff of the anterior tibial artery and the tibial-peroneal trunk. To completely expose the popliteal space, the medial attachments of the sartorius, semitendinosis, semimembrinosis and gracilis to the medial condyle of the tibia can be divided. When feasible, the pes anserinus should be reconstructed given its significant role in medial knee stabilization. Weitlaner, cerebellar retractors, flexible Adson- Beckman or Henly popliteal retractors with detachable side blades are necessary to expose the popliteal space. Typically the medial head of the gastrocnemius can be retracted down using one of these devices and does not need to be divided. [17]

Tibial Arteries

- Recommendations: Selective repair (i.e., some but not all)
- Utility of temporary shunt: Moderate
- Method/ Conduit: Ligation or interposition graft with saphenous vein

Pearls

- If a Doppler signal is present at the ankle, there is no need for additional tests or repair
- Doppler exam should be repeated as patient is resuscitated and warmed
- Repair with vein if three tibial arteries injured and an absence of a Doppler signal persists
- As long as there is at least one of the three tibial vessels intact, injuries to one or even two of the tibial vessels can safely be managed by ligation.

The recommended approach to tibial artery injury is one of selective repair (i.e. repair some but not all). Because of their distal location and redundant nature, isolated and sometimes multiple tibial artery injuries are able to be ligated without adverse outcomes. As long as one tibial artery is uninjured and patent to the ankle (i.e. an arterial signal at the ankle or foot), no additional tests or repair is required (especially at Roles 1-3). Continuous wave Doppler exam of the foot is critical in the setting of tibial artery injuries and concern for viability of the foot (i.e. patency of the remaining tibial vessel(s)). Doppler should be repeated over the first hours after injury, especially if the patient presents in shock or cold. Because of the capacity for vasoconstriction, what may initially appear as an ischemic foot from tibial vascular injury may improve with warming and resuscitation (i.e. return of arterial signal). If a signal does not return and there is concern for, or observation of, multiple tibial artery injuries, flow to the foot should be restored using a temporary shunt or interposition graft using saphenous vein.

This selective approach to tibial repair has been shown to be effective, confirming, that although tibial injuries can be ligated, there is a distinct injury pattern which requires repair. Temporary shunts may be placed in tibial vessels although success (patency) is lower than that in larger, more proximal vessels.

The anterior tibial artery is exposed through an anterolateral longitudinal incision midway between the tibia and fibula. The fascia along the lateral border of the anterior tibialis muscle is divided and the plane between the anterior tibialis and extensor digitorum longus muscles is developed. The anterior tibial artery lies along the interosseous membrane.

Exposure of the posterior tibial artery in the deep compartment of the leg is through a medial incision with a lift or "bump" under the knee or thigh. A longitudinal incision is made 2 cm posterior to the posterior margin of the tibia. Division of the tibial attachments of the soleus muscle in the proximal and mid-leg and posterior retraction of the soleus exposes the artery. Reconstruction of a peroneal artery injury is rarely required and ligation is

adequate. Importantly, tibial reconstruction is technically more challenging because of the smaller size of the vessels and may therefore take longer to complete. Like other vascular repairs, tibial reconstruction should not be undertaken if the patient has other life threatening injuries or is in extremis. [18]

Extremity Venous Injury

- Recommendations: Selective repair (i.e. some but not all)
- Utility of temporary shunt: Moderate
- Method/ Conduit: Ligation, repair or saphenous interposition graft

Pearls

- Repair of proximal veins is indicated to reduce venous hypertension and congestion.
- Shunts in proximal veins will remain patent until formal repair can be performed.
- Pneumatic compression device on distal extremity to augment venous flow after repair.

Many extremity venous injuries, especially small, distal veins, can be ligated with no adverse effects because of collateral venous drainage. However, ligation of more proximal or watershed veins, or even axial veins when collaterals have been destroyed by soft tissue wounds, will result in venous hypertension and congestion. In such instances an attempt should be made to repair the vein and restore venous outflow. Temporary shunts have been shown to be effective in restoring venous outflow in the femoral veins until formal repair can be accomplished. Techniques of lateral venorrhaphy are acceptable, although an interposition graft using saphenous vein from the uninjured limb is often necessary.

The patency of vein repairs in the lower extremity is 80% at 24 months with no increased incidence of pulmonary emboli compared to ligation. Additionally, a limb salvage benefit of vein repair compared to ligation has been shown 2 years after injury.19,20 Despite these advantages, repair of extremity venous injury should only be considered in instances when the patient's overall status is able to tolerate additional operating; otherwise venous ligation is preferred, accepting the increase in morbidity.

Technical considerations include removing thrombus from the distal venous segments with compression (e.g. ace wrap or Esmark bandage) prior to repair. Additionally, following venous repair, placement of a pneumatic compression device distal on the extremity will augment venous flow and improve patency. Lastly, if there is no contraindication, a prophylactic dose of low-molecular weight heparin should be initiated. [19]

Observation with repeat vascular exam and consider duplex or CTA at higher levels of care
Assume vascular injury and proceed to operating room or consider CTA or angiography to confirm

1. Do not release tourniquets or begin vascular injury exploration if patient is in shock from associated injuries
2. Hard signs: hemorrhage, expanding hematoma, absence of Doppler signal on repeated exam, audible bruit, palpable thrill
3. Soft signs: proximity to major vessel, fracture or dislocation patterns, diminished pulse, report of hemorrhage or shock
4. IEI is occlusion pressure of arterial Doppler signal on injured extremity divided by occlusion pressure of normal limb
   - Normal is > 0.90
   - Repeat Doppler exam and IEI during first hours after injury, especially if patient is cold and hypotensive

APPENDIX B: TORSO VASCULAR INJURY

Thoracic Aorta

- Recommendations: Selective repair
- Utility of temporary shunt: None, except in extremis
- Method/ Conduit: Observation and medical optimization or Dacron graft replacement

Pearls

- If a stable blunt injury, MEDEVAC to Role 3 for possible repair versus MEDEVAC to Role 4.
- Permissive hypotension or B-blocker may decrease risk of rupture
- If hemorrhage from penetrating wounds, entry through left 3rd or 4th interspace, one lung ventilation and rib removal to facilitate exposure of the proximal descending aorta

Management of penetrating injury to the thoracic aorta is very rare given the pre-hospital lethality of this injury. If present, management of thoracic hemorrhage in the setting of penetrating trauma is directed by chest tube location and output (i.e. the hemithorax which is bleeding from tube thoracostomy is the one which is opened). The descending thoracic aorta is approached through the left chest and when injured is surrounded by hematoma. An initial left thoracotomy can be extended into the right chest to approach the thoracic aorta by extending across the sternum ("clam shell" thoracotomy). Aortic control proximal and distal to the hematoma must be obtained including isolation or control of any intercostal arteries in this segment. Aortic clamps are used to arrest flow in this segment and the hematoma is entered with debridement of the injured aorta using scissors. An adequate length of aorta must be debrided to allow placement of large caliber (20-26mm) Dacron graft sewn end-to-end to the proximal and distal segments.

Management of blunt injury to the thoracic aorta (partial transection or pseudoaneurysm) which has reached a temporary stable equilibrium is more common. In this setting and in the absence of hemorrhage from chest tubes, contrast CT imaging is indicated to characterize the injury. Permissive hypotension and selective use of B-blockers is indicated to decrease the risk of aortic rupture during this period. If CT confirms blunt aortic injury, options include early open repair or MEDEVAC. In a patient at Role 1 or 2 with a suspected blunt aortic injury who has normal and stable vital signs and no signs of active hemorrhage from the thorax, MEDEVAC to the Role 3 should occur. At this location the decision will be made regarding options for open or endovascular repair or medical optimization and CCATT transport out of theater. Recent advances in in-theater endovascular capability have made endovascular repair of such injuries possible at certain Role 3 facilities.

Abdominal Aorta

- Recommendations: Repair
- Utility of temporary shunt: Low
- Method/ Conduit: Interposition graft / Dacron

Pearls

- Supraceliac aortic control requires high midline incision along xyphoid, spreading and suspension of rib cage with retractors and nasogastric tube in the esophagus.
- Approach supra-mesocolic Zone I hematomas with left medial visceral rotation (Mattox maneuver).
- Approach infra-mesocolic Zone I hematomas with right medial visceral rotation (Catell-Brash maneuver).

- Keep in mind that supra-mesocolic Zone I hematomas may contain transected pancreas.

Blunt and penetrating injuries to the abdominal aorta present as a central (zone I) hematoma with blood in the abdomen at laparotomy. Zone I hematomas should be considered in two locations, supra- or infra-mesocolic, and should be entered once proximal and distal control is established and blood and access are available for transfusion. Supra-mesocolic, Zone I hematomas are best approached by left medial visceral rotation (i.e. Mattox maneuver) which exposes the supraceliac, paravisceral and infrarenal segments of aorta. Infra-mesocolic Zone I hematomas should be approached with the Catell-Brash maneuver exposing the infrarenal aorta and inferior vena cava up to and behind the liver. Proximal aortic control is obtained through the gastrohepatic ligament by retracting the esophagus to the left and dividing the crus. Alternatively the Mattox maneuver exposes the supraceliac aorta from the lateral position, enabling proximal control as well. The iliac vessels or distal aorta can next be controlled, providing isolation before entering the hematoma. Repair techniques for the aorta and its branch vessels range from primary pledgetted closure to replacement with a Dacron interposition graft and depend upon the degree of injury.

Vena Cava

- Recommendations: Repair
- Utility of temporary shunt: Low
- Method/ Conduit: Lateral repair, patch angioplasty or interposition graft / ePTFE

Pearls

- Establish resuscitation lines above the diaphragm for abdominal vena cava injuries.
- Vena cava injuries should be exposed using the Catell-Brash and Kocher maneuvers.
- Lateral repair is acceptable provided that no more than 1/3rd of the lumen is compromised.
- If occlusion of the cava results in hypotension, clamp the aorta to support central perfusion.
- Retrohepatic, retroperitoneal hematomas should not be disturbed if not actively bleeding.
- Several specific strategies applicable to repair of the injured vena cava are listed in the Large Vein Injuries section (section VII).

The approach to the vena cava in the abdomen should be performed using the Cattell-Braasch and Kocher maneuvers exposing the cava, renal veins and the beginning portion of retrohepatic segment. Mobilization of the liver is required to expose the retro-hepatic vena cava; however retrohepatic hematomas should not be disturbed if there is no active bleeding.

Attempts should be made to identify large lumbar veins feeding into the injured segment which may bleed as much as the main channel of the vena cava if not controlled. Because repair of the vena cava is likely to require intermittent occlusion (i.e. sponge sticks or vascular clamps) or ligation in extreme cases, central venous access should be established above the diaphragm (i.e. subclavian or jugular veins) to allow effective volume resuscitation. If compressing or occluding the vena cava results in significant hypotension, the adjacent abdominal aorta may be temporarily occluded to support central pressures while resuscitation takes place. Repair of tangential injuries to the cava can be accomplished using lateral suture repair (i.e. running venorrhaphy) provided that the lumen is not narrowed more than ½ of its native diameter. If lateral repair results in significant narrowing, there is a higher risk of thrombosis leading to pulmonary emboli and anticoagulation should be initiated postoperatively if possible. In instances where lateral repair will result in more than 50% narrowing, patch angioplasty or resection and interposition graft using ePTFE is preferable. Ligation of the infrarenal cava is acceptable as a damage control maneuver, although this carries a significant mortality risk and major morbidity in the form of decreased cardiac preload and significant lower extremity edema. If infrarenal ligation is needed, it should always be accompanied by bilateral lower leg fasciotomies to

reduce the risk for compartment syndrome. Suprarenal occlusion of the IVC is generally not compatible with survival and should be considered a measure of last resort.24

Portal Vein and Hepatic Artery

- Recommendations: Repair
- Utility of temporary shunt: Low
- Method/ Conduit: Primary repair, patch angioplasty, interposition graft / ePTFE or Dacron or saphenous vein

Pearls

- Access to gastrohepatic ligament by Pringle maneuver should precede exploration of the porta hepatis.
- Ligation of hepatic artery injuries is acceptable if the portal vein is patent.
- Lateral venorrhaphy is preferred; ligation of portal vein results in massive bowel edema and systemic hypovolemia.
- Several specific strategies applicable to repair of the injured portal vein are listed in the Large Vein Injuries section (section VII).

Portal vein and hepatic artery injuries typically present as hematomas of the porta hepatis and should be explored after isolation of the gastrohepatic ligament and application of a Pringle maneuver. Next, careful dissection of the porta is performed to determine which structures have been injured. Injuries to the hepatic artery may be repaired with lateral suture placement if limited in severity; ligation of the hepatic artery is acceptable if the portal vein is uninjured. Repair of the portal vein should be attempted using the technique of lateral venorrhaphy if possible. If a large segment of the portal vein is damaged, vein patch angioplasty, or in rare instances, interposition vein graft may be performed. Ligation of the portal vein is an option of last resort and will result in hepatic ischemia and splanchnic congestion and hypervolemia for several days. Importantly, if the capabilities are available then imaging of the biliary system should be considered for associated injuries of the common bile duct and can be performed with cholangiography through the gall bladder.

Mesenteric Arteries

- Recommendations: Repair
- Utility of temporary shunt: Low
- Method/ Conduit: Primary repair, patch angioplasty, interposition graft / ePTFE or Dacron or saphenous vein

Pearls

- Present as supra-mesocolic Zone I hematoma.
- Repair proximal mesenteric artery and vein injuries including portal vein.
- Ligation can be performed for distal artery and vein injuries or as damage control.

Upon entering a supra-mesocolic Zone I hematoma, one may find injury to the mesenteric vessels (artery or vein). Under most circumstances, repair of the proximal superior mesenteric artery and vein, including the portal vein, is indicated using the techniques of primary pledgetted repair, vein patch angioplasty or replacement of the injured segment with interposition saphenous vein graft. The specific type of repair will depend on the location and extent of vessel injury. In cases where injury to the artery or vein is distal (i.e. beyond the middle colic artery or jejunal vein branches) or in which the patient's physiology is severely compromised, the vessels can be ligated.

Renal Arteries

- Recommendations: Selective repair
- Utility of temporary shunt: Low
- Method/ Conduit: Primary repair or patch angioplasty/Dacron or vein

Pearls

- Explore Zone II hematomas from penetrating injury.
- Establish status of contralateral kidney by contrast study or manual palpation.
- Priority is "save-life," and early nephrectomy is required with complex injuries.
- With a renal warm ischemic time > 30-60 minutes, complex repairs are not indicated.

Injury to the renal pedicle (blunt or penetrating) is closely associated with injury to the parenchyma; isolated arterial injury is rare. Essential considerations in the management of renal artery injury in wartime are the warm ischemic time of 30-60 minutes and complexity of renal artery repair. Both of these limit what the surgeon can accomplish in the context of renal artery injury other than ligation and nephrectomy.

If arterial injury manifests as occlusion with renal ischemia, it will be too late to restore flow and function to the kidney by the time the diagnosis is made in the operating room or CT scanner. If the artery is patent and bleeding, an associated Zone II or lateral hematoma requiring exploration will be present and attempts to stop hemorrhage and repair are indicated. These maneuvers may include pledgetted primary repair of the renal artery, patch angioplasty or very rarely interposition graft replacement (aorto-renal bypass). Again, considering the warm ischemic time of the kidney, complex operations to maintain or reestablish perfusion in the renal artery are not recommended and should be abandoned in favor of nephrectomy in most cases.

The method by which to approach an expanding or penetrating zone II hematoma is controversial and case specific. Isolation of the renal pedicle before exploring the hematoma is doctrine in many institutions and has the advantage of aortic isolation and definitive proximal control. However from a practical standpoint, mobilization of the damaged kidney from a lateral to medial direction without hilar control may be faster depending upon the appearance of the injury. The lateral to medial approach is similar to the medial visceral rotation performed for zone I injuries.

Iliac Arteries

- Recommendations: Repair
- Utility of temporary shunt: High
- Method/ Conduit: Interposition graft/ ePTFE or Dacron or saphenous

Pearls

- Explore Zone III hematoma from penetrating wound after establishing aortic control above the hematoma.
- Distal control is obtained at the inguinal ligament (i.e. external iliac arteries).
- Wylie hypogastric (internal iliac) clamps facilitate low-profile control of iliac arteries.

Iliac artery injuries generally present as a Zone III or pelvic hematoma with or without extremity ischemia (check femoral pulses). Exploration of the hematoma should be performed after proximal control is obtained at the infrarenal aorta and the contralateral iliac artery if possible. The distal external iliac artery should be found as it exits the pelvis at the inguinal ligament at a point where it is free from the hematoma. The internal iliac artery

may not be initially controlled or visualized before exploring the hematoma, which often requires opening to expose the internal iliac. The inability to initially control all bleeding from the hematoma necessitates preparation including multiple suction devices, Fogarty occlusion balloons (if available) direct tamponade strategies or devices and alerting anesthesia regarding the need for continued resuscitation during exploration. After proximal and distal control of the common and external iliac arteries is obtained, the hematoma is entered which facilitates exposure and clamping of the internal iliac artery and the injured vessel(s). Common and external artery injuries can be controlled and managed with a temporary vascular shunt if needed or repaired with interposition grafting using saphenous vein or prosthetic conduit (6-8mm ePTFE or Dacron). In an unstable patient or a patient where there is contamination of the field, shunt placement with definitive repair or reconstruction done at a later point is a good option.

If the primary injury is to the internal iliac artery (hypogastric), it may be ligated with 3.0 or 4.0 Prolene on an SH needle. Bleeding from associated iliac veins may be severe and difficult to expose. The iliac artery may be divided if necessary to facilitate exposure of the iliac vein, followed by repair of the artery. At certain Role 3 facilities with endovascular capabilities, selective embolization of bleeding hypogastric artery or branches is an option, particularly in blunt trauma (e.g., pelvic fracture.) The principles which apply to the management of iliac vein injury are discussed in the Management of large vein injuries section.

APPENDIX C: CERVICAL VASCULAR INJURY

Carotid Artery

- Recommendations: Repair.
- Utility of temporary shunt: High.
- Method/ Conduit: Vein patch or vein interposition graft.

Pearls

- Zone I cervical injuries best approached with median sternotomy for ample proximal exposure.
- Early control of common carotid with umbilical tape/Rummel or DeBakey clamp.
- 3 Fr Fogarty with 3-way stopcock is useful to occlude internal carotid back bleeding.
- Shunt and augment mean arterial pressure during carotid repair to perfuse brain.

Most carotid injuries result from penetrating wounds and result in hematoma. Indications for operation are bleeding or injury with interrupted flow (i.e. occlusion). When feasible, contrast CT should be performed for neck wounds. CT aids in the triage for urgent operation, improves operative planning and images the brain as a baseline. Although a selective approach to exploration of zone II neck wounds is acceptable, if a carotid injury is identified, the neck should be explored and an attempt made to repair. The exceptions are blunt injury resulting in carotid occlusion greater than 12 hours or a zone III injury not accessible by standard techniques.

Exposure of the carotid artery is through a generous incision coursing anterior to the sternocleidomastoid and facilitated by a roll under the shoulders, extension of the neck and turning of the head away from the injury. The platysma is divided and the sternocleidomastoid muscle reflected posterolaterally. The internal jugular vein is carefully dissected and mobilized laterally, exposing the carotid artery. The carotid is exposed proximal to the hematoma and controlled with an umbilical tape into a Rummel device (i.e. red rubber catheter). In the absence of uncontrolled bleeding, there is no need to tighten the Rummel; but having it in place gives one this option and allows for securing the proximal end of a temporary shunt.

The dissection proceeds distal into the zone of injury. If bleeding is encountered the Rummel may be cinched or a clamp (angled DeBakey) slid proximal to the umbilical tape using it to pull the carotid up into the clamp, thereby avoiding injury to the vagus nerve. Back bleeding from the internal carotid artery is a favorable sign and can be controlled with a small clamp or a (3 Fr) Fogarty inserted into the internal and inflated using a 1cc syringe and 3-way stop-cock to maintain inflation. The external carotid artery is controlled with vessel loops or ligated. If the internal and common carotid arteries are controlled above and below the injury, a temporary shunt can be placed to maintain perfusion while the injury is identified and options considered. First, the shunt should be placed into the internal carotid artery and secured with a vessel loop or small Javid shunt clamp allowing back bleeding through the shunt. To secure the proximal shunt, an angled DeBakey is placed proximal to the umbilical tape and Rummel device. Then in sequence, the shunt is placed in the common carotid through the Rummel which is partially tightened around the shunt. As it is advanced deeper (more proximal) into the common carotid, the DeBakey clamp is slowly opened allowing the shunt to pass while the Rummel is tightened down fully securing the shunt in place. Alternatively the common carotid artery can be controlled with fingers as the shunt is inserted proximal and the Rummel synched down. If available, Javid shunt clamps can be used to occlude the artery around the shunt instead of the Rummel device.

Repair of carotid artery injuries most commonly requires placement of an interposition saphenous vein graft, although primary repair or vein patch angioplasty can be performed for less severe injuries. To perform the interposition graft over the shunt, the proximal end is removed using the DeBakey clamp to again occlude the common carotid proximal to the Rummel. The vein graft is next placed over the shunt (i.e. shunt in the vein graft lumen). The proximal shunt is reinserted into the common carotid and secured with the Rummel using

previously described sequence. After flow is restored in the shunt, the distal vein graft anastomosis is performed using 6-0 Prolene to the edge of the normal internal carotid. Next the proximal anastomosis to the common is started also with 6-0 Prolene. When the anastomosis is nearly completed, the shunt is removed through the remaining anastomotic opening, first removing the proximal from the common carotid and observing back bleeding from the shunt in the internal carotid. Finally the shunt is removed from the internal and the vein graft flushed generously with heparinized saline and the anastomosis completed. Alternatively the reconstruction can be performed without a shunt, however, this exposes the ipsilateral hemisphere to prolonged ischemia. Regardless of whether or not a shunt is used, the mean arterial pressure should be kept above 90mmHg during the repair to optimize cerebral perfusion.

Alternatively the reconstruction can be performed without a shunt, however, this exposes the ipsilateral hemisphere to prolonged ischemia. Regardless of whether or not a shunt is used, the mean arterial pressure should be kept above 90mmHg during the repair to optimize cerebral perfusion. If no other life threatening injuries are present, a small amount (50u/kg) of systemic heparin is recommended along with generous flushing of the repair with heparinized saline to prevent platelet aggregation and clot formation. Ligation of the internal carotid artery is an acceptable damage control maneuver to stop hemorrhage but has an acute stroke rate of 30-50%.

If no other life threatening injuries are present, a small amount (50u/kg) of systemic heparin is recommended along with generous flushing of the repair with heparinized saline to prevent platelet aggregation and clot formation. Ligation of the internal carotid artery is an acceptable damage control maneuver to stop hemorrhage but has an acute stroke rate of 30-50%.

Vertebral Artery

- Recommendations: Ligate
- Utility of temporary shunt: None
- Method/ Conduit: N/A

Pearls

- Bleeding vertebral artery injuries are ligated with no role for reconstruction in theater.
- Vertebral artery occlusions are managed with anticoagulation if it is not contraindicated.
- Endovascular embolization is an option if injury is not accessible by standard exposure.

Repair of vertebral artery injuries in wartime is extremely rare and most commonly bleeding from this vessel is ligated as a matter of necessity during neck exploration. Alternatively, vertebral artery injury (occlusion or extravasation) can be discovered on a contrast CT scan. There should be a high index of suspicion for this injury with cervical spine fractures. In instances of acute vertebral artery occlusion, anticoagulation is recommended to reduce the risk of posterior circulation stroke although the clinical evidence to support this is limited. If associated injuries preclude use of systemic heparin, then antiplatelet therapy should be initiated.

Jugular Vein

- Recommendations: Selective repair
- Utility of temporary shunt: None
- Method/ Conduit: Lateral venorrhaphy, vein patch or saphenous vein

Pearls

- Significant jugular vein injuries can be ligated without adverse effects.
- Repair of jugular injuries should be considered in the setting of TBI with elevated ICP.

Repair instead of ligation of jugular vein injuries may be indicated in instances of associate closed head injury to reduce intracranial pressures, although little data exists to support this practice. Minor jugular vein injuries can be repaired by lateral suture repair (venorrhaphy) while patch angioplasty or interposition vein graft are options for more extensive injuries. Operative exposure of the jugular vein is the same as that described for the carotid artery.

APPENDIX D: MISCELLANEOUS TOPICS

LARGE VEIN INJURIES

Pearls

1. **Formal control (DeBakey clamps) is acceptable** but may be difficult or not advisable as it risks causing injury or may not be needed if injury is limited to the side wall of the vein.
2. **Initial control** can be accomplished by one or more fingers on the bleeding segment.
3. **Organize the operating room and confirm availability of blood and central venous access.**
4. **Venous access** above the heart if operating on injury to the inferior vena cava.
5. **Optimal lighting**, exposure (i.e. extend incisions) and two or more suction devices.
6. **Avoid too small of a needle and suture** which are difficult to maneuver in blood. 4-0 Prolene on an SH tapered needle is substantive suture on a needle large enough to see.
7. **Fingers replaced with a low profile tampanode device** such as a small sponge stick or Wecksorb "K" dissector (i.e. Kitner device) as bleeding is evacuated.
8. **Passes of suture are made** capturing muscle or soft tissue if possible (i.e. pledget-effect). Tie the knot to begin running venorrhaphy or place second pass in "figure-of-8" fashion.
9. **Felt pledgets can be used,** but may not be available.
10. **Hemorrhage control with ligation** is preferable to patency with death from exsanguination.

LIGATION OF VESSELS

Pearls

1. **Acceptable damage control maneuver** especially for small, more distal arteries and veins
2. **Temporary vascular shunting** to restore perfusion should be considered before ligation
3. **Continuous wave Doppler** should be checked before ligation to judge perfusion/viability

Ligation of vascular injuries was the mainstay of treatment for centuries and should not be overlooked as a damage control option; especially at Role 2 facilities where operations are best abbreviated (≤ 1 hr). This technique is especially useful in small distal vessels (tibial, forearm and arm below the take-off of the profunda brachial artery) when patients are in extremis. Use of temporary vascular shunts or even repair should be considered before ligation, however, if not available or feasible ligation should be completed. Continuous wave Doppler may also be useful in assessing perfusion to the extremity distal to the vessel in question.

FOGARTY THROMBECTOMY CATHETERS

Pearls

1. Sized at 2-7 Fr; **maximum balloon diameter** of the 2 and 3 Fr catheters is 4 and 5 mm.
2. **Inflate with saline** using 1cc tuberculin syringe (0.2-0.75cc) while withdrawing from vessel.
3. **Goal is clot, not intima,** removal so don't over-inflate or "drag" too much.
4. **May be used to control bleeding** with use of a 3-way stop cock to maintain inflation.

Fogarty catheters are a key tool in the armamentarium of vascular injury management. Used primarily to remove thrombus, they can also be used to arrest bleeding from within the lumen of the vessel. The most common size used in extremity vascular injury is 2 and 3 Fr although the maximum inflated diameter of the 4 Fr Fogarty catheter is 9 mm which can be used for balloon occlusion of the femoral and iliac vessels. At least one pass of a Fogarty should precede extremity vascular injury repair to assure removal of the traumatic thrombus burden before restoring inflow and outflow. The key tenet is not to cause native vessel damage. To lessen the risk of damage, avoid advancing the catheter too distal in the smaller vessels of the leg and arm and avoid over aggressive, static balloon inflation (i.e. angioplasty or "intimectomy"). Using a Fogarty balloon to control bleeding from within the vessel lumen requires a 3-way stop cock to maintain inflation once the bleeding has been stopped.

TEMPORARY VASCULAR SHUNTS

Pearls

1. Inline shunts rest in the vessel ("in-situ") while long external shunts are designed to loop.
2. In-line Argyl shunts come in cylinder container with 8, 10, 12 and 14 Fr sizes.
3. In-line Javid shunts are longer and individually packaged.
4. Sundt shunts are designed with short (15cm; inline) and long (30cm; external) profiles.
5. Equal success has been had with Argyl, Javid and Sundt without systemic anticoagulation.
6. Secured with silk ligatures, patent for up to 6 hours; reports of longer duration exist.
7. Shunts should be removed with formal repair in-theater prior to medevac to Role 4.

Temporary vascular shunts are effective and should be considered in the management of nearly all extremity vascular injury patterns including proximal venous injuries. Their main advantage is provision of early restoration of flow and mitigation of the damaging effects of arterial ischemia and venous hypertension. As an abbreviated procedure compared to formal vascular repair, shunting extends the window of opportunity for limb salvage in some patterns of vascular injury. Although the patency at 3-4 hours is higher in larger, more proximal vessels (axillary/brachial and femoral/popliteal), shunts have been used effectively in smaller (distal brachial/forearm and tibial) vessels. Outcomes of extremity vascular injury managed with temporary shunts have been recorded demonstrating no adverse effect of this technique and a limb salvage advantage in the most severely injured limbs (MESS ≥ 8). [2, 5, 20]

PEDIATRIC VASCULAR INJURIES

Pearls

1. Intervention should be avoided in those less than 10 years old given propensity for spasm.
2. Ligation is more well tolerated in infants and toddlers given ability to recruit collaterals.
3. Perform interrupted suture lines (6-0 Prolene) to allow expansion with growth of child.

Although rare, deployed surgeons can expect to see young patients with vascular injury. Intervention of any type, including angiography, should be avoided in those less than 5 years even if an extremity appears ischemic (i.e. without Doppler signal). The small size of arteries in children and their propensity for vasospasm makes it more likely that an intervention will do harm or confuse the clinical scenario rather than improve the situation. Because of the ability of children to tolerate relative limb ischemia and to develop collateral circulation, ligation of bleeding vessels alone is recommended with warming of the extremity and resuscitation. In rare cases, in children older than 8, reconstruction of larger proximal arteries can be accomplished using reversed saphenous

vein. In such instances, the anastomosis should be performed using interrupted suture allowing expansion as the child grows. 16

ENDOVASCULAR CAPABILITY & INFERIOR VENA CAVA FILTERS

(See Trauma-Specific Endovascular Inventory Tables) [14]

Pearls

1. Techniques should be used in a small subset of injuries and directed by a trauma surgeon.
2. Indications for vena cava filter include inability to initiate chemoprophylaxis within 48 hours of injury and the occurrence of pulmonary embolus while on chemoprophylaxis.

The emergence of catheter based, endovascular technology to manage injury in the civilian setting has been expanded to the wartime setting. Although advantageous in a small set of combat injuries, endovascular capability in austere settings is in its early stages and its application should be directed by appropriately trained surgeons or interventional radiologists. Injury patterns and procedures which lend themselves to endovascular techniques include central injuries of the thoracic aorta and brachiocephalic vessels (subclavian and carotid) and select patterns of solid organ and pelvic injury amenable to coil embolization. Placement of vena cava filters to reduce the risk of pulmonary thromboembolic events is indicated in patients who cannot receive chemoprophylaxis or therapy with heparin. A trauma specific endovascular inventory for in-theater capability is listed in Trauma-Specific Endovascular Inventory Tables.

Indications for placement of an inferior vena cava filter include an inability to initiate chemoprophylaxis with low molecular weight heparin within 48 hours of a significant injury and the occurrence of a pulmonary embolus while on chemoprophylaxis. Examples of contraindications to chemoprophylaxis include significant traumatic brain, solid organ or pelvic injuries with bleeding. The Günther-Tulip™ (Cook Medical, Inc.) filter is currently recommended because of its established record of success and it ability to be removed in certain circumstances. (See Trauma-Specific Endovascular Inventory Tables.)

USE OF PROSTHETIC GRAFT MATERIAL

Pearls

1. **ePTFE (Gortex) or Dacron** used for central torso vascular injuries (aorta, great vessels).
2. **Prosthetic conduit acceptable as last resort** in extremities when vein cannot be harvested.
3. **If prosthetic used in extremity injury, notify higher levels of care to facilitate surveillance.**

Prosthetic graft materials such as ePTFE (Gortex) or Dacron should be reserved for open reconstruction of the aorta and large torso vessels and used very rarely as conduit for extremity vascular injury. Wartime experience has demonstrated poor incorporation of prosthetic grafts in extremity wounds and a propensity for infection compared to saphenous vein. Additionally, extrapolation of civilian data suggests improved patency of vascular reconstructions using saphenous vein. In the rare instance (i.e. damage control) when prosthetic conduit is used for extremity vascular injury, communication with higher levels of care should occur so that appropriate surveillance or even removal of the graft and replacement with vein can occur. [2]

HARVESTING & USE OF AUTOLOGOUS VEIN

Pearls

1. Use reversed greater saphenous vein from uninjured extremity.
2. Expose at saphenofemoral junction or anterior to medial maleolus (consistent locations).
3. Be sure to mark anatomically distal end as "in-flow" assuring reversal of vein conduit.
4. Introduce 18 ga. plastic vein or metallic olive tip cannula to distend with heparin saline.

Because of its versatility, resistance to infection, propensity for tissue incorporation and favorable patency rates, saphenous vein for interposition graft or patch material is favored. The greater saphenous vein s may be consistently located at the saphenofemoral junction (2cm medial to the pubic tubercle) or 1-2 cm anterior to the medial malleolus. Identifying the actual saphenofemoral junction is important to confirm that the vein being exposed is truly the main channel saphenous and not an accessory branch or anterior saphenous (i.e. must follow back to main saphenofemoral junction). Nearly always in the setting of trauma the vein appears in-situ as "too small" or "not adequate" due to vasoconstriction or spasm.

Nonetheless, after confirming that the vein being exposed is the main channel saphenous, the specimen should be removed and dilated on the back table with firm infusion of heparin saline using a 14-18 gauge plastic vein cannula or the metallic olive tip cannula. Persistence and this maneuver almost always results in a markedly improved and dilated vein ready to be used for repair. Reversal of the vein must also be confirmed as venous valves will not permit flow in a retrograde fashion.

SOFT TISSUE COVERAGE & ANASTAMOTIC DISRUPTION

Pearls

1. **Cover vascular repairs** with available, viable local tissue (muscle and adipose)
2. If no soft tissue to cover, **route grafts** out of zone of injury.
3. A poorly covered **vascular anastamosis** can "blowout," but not in the early (< 5 day) period.
4. **Avoid direct placement of negative pressure** wound therapy sponge on vascular structures.

Soft tissue coverage of vascular repairs is required to assure incorporation and prevent infection and blowout. Option 1 is to immediately cover the repair with viable local soft tissue (muscle and adipose). The negative pressure wound therapy device (VAC®, Kinetic Concepts Inc.) is useful on top of such coverage as it provides a closed dressing which removes wound effluent and decreases bacterial counts. This wound adjunct has been found to assist with accomplishing delayed primary closure of soft tissue wounds over vascular repairs or coverage with skin grafts. The reticulated open-cell foam sponge of the VAC® should not be placed directly on vessels, however when used over viable tissue covering the vascular repair, VAC® has resulted in excellent outcomes with no increase in graft-related complications or blowouts.

If no tissue is available to cover the vascular repair, one can route an interposition graft out of the zone of injury through another myocutaneous or even subcutaneous path. As a last resort, the vascular reconstruction can be left with marginal coverage at Role 2 and 3 facilities; however in these cases close examination must occur at Role 4 facilities. In these rare instances higher levels of care should pursue transfer of viable tissue from other locations (sartorius, rectus abdominis or other muscle) in order to definitively cover the repair within 5-7 days. Although it is acceptable for Role 2 and 3 providers to leave a graft with uncertain coverage, the onus of care then falls heavily on Role 4 facilities to inspect, cover, re-route or even ligate the graft to reduce the risk of catastrophic blowout.

It is important to recognize that even in the best of civilian and wartime circumstances that there has been historically and remains currently a finite risk of anastomotic disruption. Using the management strategies described above the risk of graft blowout has been within an acceptably low range of 1-2% throughout the wars in Iraq and Afghanistan. [15, 23]

ANTICOAGULATION/RECOMBINANT FACTOR VII USE

Pearls

1. **Heparin saline is typically 1000u/liter** although other mixtures with or without papaverine are acceptable; there is no evidence that other 'vein solutions' offer any advantage.
2. **Systemic anticoagulation** is achieved with 50 u/kg of IV heparin with1000 u repeated at 1 hr; repeat doses are not recommended given the propensity for bleeding in wartime injury.
3. **"Regional anticoagulation"** is the use of heparin saline flush in the inflow/outflow vessels.
4. The **use of recombinant factor VII** is no longer recommended

TRAUMA-SPECIFIC ENDOVASCULAR INVENTORY TABLES

Table 1. Imaging Systems, Endovascular Accessories, Wires and Sheaths

APPENDIX E: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Ventilator Associated Pneumonia (VAP) (CPG ID:45)

To establish guidance for the prevention and mitigation of Ventilator Associated Pneumonia (VAP)

JTS CPGs are developed and peer reviewed by subject matter experts serving on the Defense Committees on Trauma: the Committee on Tactical Combat Casualty Care; the Committee of Surgical Combat Casualty Care; and the Committee of En Route Combat Casualty Care. Special thanks goes to these individuals who donate their time and share their experience to aid the JTS mission of publishing standardized clinical practice guidelines which improve patient care and save lives.

GOAL

The goal of this Clinical Practice Guideline (CPG) is to provide guidance for the diagnosis, treatment, prevention, and mitigation of Ventilator Associated Pneumonia (VAP). These guidelines are not intended solely for clinical care, but also to help unit commanders and supporting medical components to consider the unique challenges of the management of a common healthcare associated infection in both traditional and expeditionary settings.

BACKGROUND

VAP is a common healthcare-associated infection (HAI), but what defines VAP and how it is diagnosed have remained moving targets. Due to wide variations in the surveillance and diagnosis of VAP, the true rate of VAP is unknown, but it is believed to occur in at least 5-15% of patients placed on a ventilator.[1-2]

While much of combat casualty care in the intensive care unit setting is largely similar to the care of trauma patients in civilian centers, there are several challenges unique to expeditionary care, chief among them being microbiological variabilities. Military operations in Iraq and Afghanistan are notable for a high number of multi-drug resistant (MDR) bacterial infections in combat casualties, particularly Acinetobacter calcoaceticus-baumannii complex (ABC).[3]

Several benchmark studies, along with other data, implicate nosocomial transmission as the major contributing source of these infections.[4-6] *An outbreak of multi-drug resistant Acinetobacter baumannii-calcoaceticus complex infections in the U.S. military health-care system associated with military operations in Iraq* described cluster outbreak strains of ABC within the military healthcare system suggesting that, at least in the case of ABC, the bacteria has spread from field hospitals in Iraq to those within the continental U.S.[7] Additionally, bacteria identical to those found in clinical isolates have been cultured from numerous environmental surfaces from U.S. medical treatment facilities within Iraq. These experiences have been replicated in more recent times with similar results, indicating that this issue is endemic and not related to individuals or groups of service members.

DIAGNOSIS

The diagnosis of VAP is difficult and varies across institutions. American Thoracic Society and Infectious Disease Society of America guidelines define VAP as a "new lung infiltrate plus clinical evidence that the infiltrate is of an infectious origin, which include the new onset of fever, purulent sputum, leukocytosis, and decline in oxygenation" which develops >48 hours after endotracheal intubation.[8]

Determination of whether a pulmonary abnormality is of infectious origin is particularly challenging, especially in trauma patients. Blast injury and penetrating chest injury patients are highly likely to have injury-related chest radiography findings that may obscure or mimic infections.

Patients on mechanical ventilation are at risk for a variety of serious complications in addition to VAP, including acute respiratory distress syndrome, pneumothorax, pulmonary embolism, lobar atelectasis, and pulmonary edema. The Centers for Disease Control have large scale, ongoing quality projects designed to validate and streamline surveillance measures, though these have yet to be validated for a priori diagnosis of various ventilator associated conditions. Despite the changing language surrounding ventilator associated conditions, the strongest and most consistent evidence continues to support daily

sedation interruptions and spontaneous breathing trials for aggressive liberation from mechanical ventilation as the factors most likely to reduce all ventilator associated conditions.[9]

PROPHYLACTIC MEASURES

GENERAL MEASURES:

1. Conduct active surveillance for ventilator associated conditions,[10] including but not limited to:
   - Ventilator associated pneumonia
   - Pulmonary edema
   - Acute respiratory distress syndrome
   - Atelectasis
2. Perform daily assessments of readiness for extubation including:
   - Daily sedation interruptions for patients in whom it is not contra-indicated (e.g., severe cerebral edema).
   - Protocoled conduction of spontaneous breathing trials for all patients meeting the following criteria:

   Required criteria

   a. The cause of the respiratory failure has improved.

   b. PaO2/FiO2 ≥150 or SpO2 ≥90 percent on FiO2 ≤ 50 percent and positive end-expiratory pressure (PEEP) ≤ 8 cmH2O

   c. pH >7.25

   d. Hemodynamic stability (no or low dose vasopressor medications)

   e. Able to initiate a spontaneous inspiratory effort.

   Additional criteria (optional criteria)

   a. Hemoglobin ≥7 mg/dL

   b. Core temperature ≤38 to 38.5°Centigrade

   c. Mental status awake and alert or easily arousable with ability to protect airway.

STAFF EDUCATION PRIORITIES

1. Epidemiology of Ventilator Associated Events
2. Infection-control procedures for prevention of VAP

   a. Avoid intubation and utilize non-invasive ventilation when possible.

   b. ABCDEF bundle[11] (see Appendix C)

   c. VAP bundle components and use[12] (See below.)

3. Periodic audits of the use of guidelines with aggressive education and enforcement of procedures.

VAP BUNDLE COMPONENTS

RESPIRATORY EQUIPMENT MANAGEMENT

Breathing Circuits with Humidifiers

Change the circuit when it is visibly soiled or mechanically malfunctioning. Do not routinely change on the basis of duration of use of the breathing circuit (i.e. ventilator tubing and exhalation valve and the attached humidifier) that is in use on an individual patient.

Breathing Circuit/Tubing Condensation

Periodically drain and discard any condensation that collects in the tubing of mechanical ventilators, taking precautions not to allow condensation to drain toward the patient. Wear gloves to perform the procedure and/or when handling the fluid. Decontaminate hands with soap and water (if hands are visibly soiled) or with an alcohol-based hand solution before and after performing the procedure or handling the fluid.

Humidifiers

Use sterile (not distilled, nonsterile) water to fill bubbling humidifiers. Between the uses of reusable hand-powered resuscitation bags on different patients, sterilize or subject to high-level disinfection. Do not routinely sterilize or disinfect the internal machinery of anesthesia equipment. Between uses on different patients, clean reusable components of the breathing system or patient circuit (e.g., tracheal tube or face mask) inspiratory and expiratory breathing tubing, y-piece, reservoir bag, humidifier, and tubing, and then sterilize or subject them to high-level liquid chemical disinfection or pasteurization in accordance with the device manufacturers' instructions for their reprocessing.

Keep all ventilators covered when not in use to reduce dust accumulation on devices.

PREVENTION OF PERSON-TO-PERSON TRANSMISSION OF BACTERIA

Cohorting

Implement patient and staff cohorting whenever possible by using geographically distinct areas of care. In the deployed setting, this includes separating Host National from non-Host National patient due to differences in the microbiomes. Disinfect all patient care equipment after each patient transfer. Terminally clean rooms between patients and consider periodic (monthly) ICU/ICU subunit closure for thorough cleaning and disinfection. In deployed settings, this should be conducted as regularly as field conditions permit.

Standard Precautions

Decontaminate hands by washing either with antimicrobial soap and water (if hands are visibly dirty or contaminated with blood or body fluids), or by using an alcohol-based waterless antiseptic agent if hands are not visibly soiled. Use personal protective equipment based on clinical circumstance.

Contact precautions with gloves and gown for all patient contact for patients infected or suspected with epidemiologically significant pathogens, specifically MDR Acinetobacter spp., ESBL-producing Klebsiella spp. and Escherichia coli, carbapenem-resistant Enterobacteriaceae, vancomycin-resistant Enterococcus spp., and methicillin-resistant Staphylococcus aureus. Decontaminate hands before and after patient contact and use gloves as below.

Gloves

Wear gloves for handling secretions or objects contaminated with secretions of any patient. Change gloves and decontaminate hands as described previously between contacts with different patients. When anticipating becoming soiled from secretions, wear a gown and change it after soiling occurs and before providing care to another patient.

Care of patients with Tracheostomy

Perform tracheostomy care under aseptic conditions. When changing a tracheostomy tube, wear a gown and mask, use aseptic technique. Providers should familiarize themselves with manufacturers recommendations regarding the quality and frequency recommended for tracheostomy care. Additionally, the life expectancy of inner cannula is variable depending on the product used (e.g., 24h to 29 days). Tracheostomy care orders should be written specific to the product used.

Suctioning of respiratory tract secretions

Appropriate to use either the multiuse closed system suction (Ballard) catheter or the single-use open system suction catheter. Patients persistently on the ventilator should have a Ballard system in line, while those intermittently on or off the ventilator with a tracheostomy in place can have the open suction employed as appropriate. If the open-system suction is employed, use a sterile, single-use catheter and sterile technique when suctioning. Use only sterile fluid to remove secretions from the suction catheter if the catheter is to be used for re-entry into the patient's lower respiratory tract.

PREVENTION OF MUCUS PLUGGING (ENDOTRACHEAL TUBE)

- If feasible, use an endotracheal tube (Hi Lo Tube) with a dorsal lumen above the endotracheal cuff to allow drainage of tracheal secretions that accumulate in the patient's subglottic area.
- Before deflating the cuff of an endotracheal tube in preparation for extubation, ensure that secretions are cleared from above the tube cuff.

PREVENTION OF ASPIRATION RELATED INFECTION (GASTROINTESTINAL)

- Head of bed elevation: In the absence of contraindication(s), elevate the head of bed at an angle of 30° to 45° of a patient at high risk for aspiration (e.g., traumatic brain injury, mechanically assisted ventilation).
- As soon as the clinical indications for their use are resolved, remove devices such as endotracheal, tracheostomy, and/or enteral tubes from patients.
- Feeding tube verification: Verify appropriate placement of the feeding tube prior to use.
- Due to recent studies questioning the value and safety[12] of chlorhexidine-based oral care, this guideline does not advocate for the routine use of chlorhexidine-based oral decontamination.

Routine oral hygiene with a tooth brush or oral sponge should continue to be provided with the goals of removal of dental plaque and other debris from teeth, tongue and oral mucosa.

PREVENTION OF POSTOPERATIVE PNEUMONIA

- Encourage all postoperative patients to take deep breaths, move about the bed, and ambulate unless medically contraindicated.
- Use incentive spirometry on postoperative patients.
- Incorporate rehabilitation therapy as early as possible in the post-operative period.
- Antibiotic therapy:
  - Surgical prophylaxis: Minimize the duration and spectrum of surgical antibiotic prophylaxis in accordance with the JTS Infection Prevention Clinical Practice Guideline, 08 Aug 2016.13
  - Suspected infection: Initial therapy should be broad spectrum and informed by each facility's antibiotic susceptibility patterns, if available. When possible, cultures should be obtained prior to initiation of antibiotic therapy. Infectious Disease Society of America guidelines state that non-invasive sampling with semi-quantitative cultures is the preferred methodology. Therapy should be tailored based on culture results and should be given for a 7 day course.14

AEROMEDICAL EVACUATION CONSIDERATIONS

1. Aeromedical Evacuation from any AOR to CONUS can require multiple flights over the course of days before the patient arrives at his or her final destination.
2. All patients, including those on mechanical ventilation, will experience a decrease in PaO2 as ambient pressure decreases.
   - Patients with marginal gas exchange will require additional support during flight.
   - Cabin altitude restriction will lessen the impact on gas exchange.
3. All ventilated patients should have the head of bed elevated at least 30° unless there is a contraindication.
4. All ventilated patients require gastric decompression prior to flight. Barring specific surgical indications for nasal placement, orogastric tube is preferred to nasogastric tube to prevent sinusitis.
5. If NPO or not tolerating fluids, consider adding IV fluids to help prevent dehydration during flight. Consider increasing maintenance IV rate due to dry air at altitude and increased rate of insensible loss.
6. Consider repeat CXR prior to flight if > 12 hours has elapsed since most recent one or clinical condition has changed significantly.
7. Do not extubate patient less than 4 hours prior to take off.
8. Consider enteral nutrition according to JTS Nutritional Support Using Enteral and Parenteral Methods CPG.[15] Tube feeds not administered through a small bowel feeding tube should be discontinued prior to flight.

9. Patients with decreased mobility require routine Deep Venous Thrombosis prophylaxis. See the JTS CPG The Prevention of Deep Venous Thrombosis – Inferior Vena Cava Filter, 02 Aug 2016.[16]
    - If anatomically feasible, sequential compression devices should be used.
    - Enoxaparin 30mg sq BID or heparin 5000 IU sq q8h may be used as chemoprophylaxis providing patient does not have potential hemorrhagic issues.
10. Gastric ulcer prevention should be provided if indicated

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

All patients receiving mechanical ventilation.

INTENT (EXPECTED OUTCOMES)

- Incidence of VAP is tracked in each ICU and for the system as a whole.
- Mechanically ventilated patients receive VAP bundle.

PERFORMANCE/ADHERENCE METRICS

- Number and percentage of mechanically ventilated patients who develop VAP, tracked for each role 3 and 4 separately and overall for the system as a whole.
- Number and percentage of patients who have daily sedation interruption and spontaneous breathing trial or contraindication documented.

DATA SOURCES

- Patient Record
- Department of Defense Trauma Registry (DoDTR)

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the Joint Trauma System (JTS) Director, JTS Program Manager, and the JTS PI Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local level with this CPG.

APPENDIX A: VENTILATOR-ASSOCIATED EVENTS SURVEILLANCE ALGORITHM

Patient has a baseline period of stability or improvement on the ventilator, defined by ≥ 2 calendar days of stable or decreasing daily minimum* FiO_2 or PEEP values. The baseline period is defined as the 2 calendar days immediately preceding the first day of increased daily minimum PEEP or FiO_2. *Daily minimum defined by lowest value of FiO_2 or PEEP during a calendar day that is maintained for > 1 hour.

After a period of stability or improvement on the ventilator, the patient has at least one of the following indicators of worsening oxygenation:
1) Increase in daily minimum* FiO_2 of ≥ 0.20 (20 points) over the daily minimum FiO_2 of the first day in the baseline period, sustained for ≥ 2 calendar days.
2) Increase in daily minimum* PEEP values of ≥ 3 cmH_2O over the daily minimum PEEP of the first day in the baseline period† , sustained for ≥ 2 calendar days.
*Daily minimum defined by lowest value of FiO_2 or PEEP during a calendar day that is maintained for > 1 hour. †Daily minimum PEEP values of 0-5 cmH_2O are considered equivalent for the purposes of VAE surveillance

Ventilator-Associated Complication (VAC)

On or after calendar day 3 of mechanical ventilation and within 2 calendar days before or after the onset of worsening oxygenation, the patient meets both of the following criteria:
1) Temperature > 38 °C or < 36°C, OR white blood cell count ≥ 12,000 cells/mm^3 or ≤ 4,000 cells/mm^3
2) A new antimicrobial agent(s) (see Appendix B for eligible antimicrobial agents) is started, and is continued for ≥ 4 qualifying antimicrobial days.

Infection-related Ventilator-Associated Complication (IVAC)

On or after calendar day 3 of mechanical ventilation and within 2 calendar days before or after the onset of worsening oxygenation, ONE of the following criteria is met (taking into account organism exclusions specified in the protocol):
1) Criterion 1: Positive culture of one of the following specimens, meeting quantitative or semi-quantitative thresholds† as outlined in protocol, without requirement for purulent respiratory secretions:
- Endotracheal aspirate, ≥ 10^5 CFU/ml or corresponding semi-quantitative result
- Bronchoalveolar lavage, ≥ 10^4 CFU/ml or corresponding semi-quantitative result
- Lung tissue, ≥ 10^4 CFU/g or corresponding semi-quantitative result
- Protected specimen brush, ≥ 10^3 CFU/ml or corresponding semi-quantitative result

2) Criterion 2: Purulent respiratory secretions (defined as secretions from the lungs, bronchi, or trachea that contain >25 neutrophils and <10 squamous epithelial cells per low power field [lpf, x100])† **PLUS** organism identified from one of the following specimens (to include qualitative culture, or quantitative/semi-quantitative culture without sufficient growth to meet criterion #1):
- Sputum
- Endotracheal aspirate
- Bronchoalveolar lavage
- Lung tissue
- Protected specimen brush

3) Criterion 3: One of the following positive tests:
- Organism identified from pleural fluid (where specimen was obtained during thoracentesis or initial placement of chest tube and NOT from an indwelling chest tube)
- Lung histopathology, defined as: 1) abscess formation or foci of consolidation with intense neutrophil accumulation in bronchioles and alveoli; 2) evidence of lung parenchyma invasion by fungi (hyphae, pseudohyphae or yeast forms); 3) evidence of infection with the viral pathogens listed below based on results of immunohistochemical assays, cytology, or microscopy performed on lung tissue
- Diagnostic test for Legionella species
- Diagnostic test on respiratory secretions for influenza virus, respiratory syncytial virus, adenovirus, parainfluenza virus, rhinovirus, human metapneumovirus, coronavirus

† If the laboratory reports semi-quantitative results, those results must correspond to the quantitative thresholds.

Possible Ventilator-Associated Pneumonia (PVAP)

APPENDIX B: ANTIMICROBIALS AGENTS ELIGIBLE FOR IVAC, PVAP

Antimicrobials Agents Eligible for IVAC, PVAP	
1. Amikacin	35. Gentamicin
2. Amphotericin B	36. Imipenem/Cilastatin Isavuconazonium
3. Amphotericin B Liposomal	37. Itraconazole
4. Ampicillin	38. Levofloxacin
5. Ampicillin/Sulbactam	39. Linezolid
6. Anidulafungin	40. Meropenem
7. Azithromycin	41. Meropenem/Vaborbactam
8. Aztreonam	42. Metronidazole
9. Baloxavir Marboxil	43. Micafungin
10. Caspofungin	44. Minocycline
11. Cefazolin	45. Moxifloxacin
12. Cefepime	46. Nafcillin
13. Cefotaxime	47. Omadacycline
14. Cefotetan	48. Oritavancin
15. Cefoxitin	49. Oseltamivir
16. Ceftaroline	50. Oxacillin
17. Ceftazidime	51. Penicillin G
18. Ceftazidime/Avibactam	52. Peramivir
19. Ceftolozane/Tazobactam	53. Piperacillin
20. Ceftriaxone	54. Piperacillin/Tazobactam
21. Cefuroxime	55. Plazomicin
22. Ciprofloxacin	56. Polymyxin B
23. Clarithromycin	57. Posaconazole
24. Clindamycin	58. Quinupristin/Dalfopristin
25. Colistimethate	59. Rifampin
26. Dalbavancin	60. Sulfamethoxazole/Trimethoprim
27. Delafloxacin	61. Tedizolid
28. Doripenem	62. Telavancin
29. Doxycycline	63. Tetracycline
30. Eravacycline	64. Tigecycline
31. Ertapenem	65. Tobramycin
32. Fluconazole	66. Vancomyin, Intravenous Only
33. Fosfomycin	67. Voriconazole
34. Gemifloxacin	68. Zanamivir

APPENDIX C: ABCDEF BUNDLE

A: Assess, prevent and manage pain

B: Both Spontaneous Awakening Trials (SAT) and Spontaneous Breathing Trials (SBT)

C: Choice of analgesia and sedation

D: Delirium: Assess, Prevent and Manage

E: Early mobility and exercise

F: Family engagement and empowerment (challenging in the deployed environment)

The ABCDEF Bundle: Science and Philosophy of How ICU Liberation Serves Patients and Families, Ely EW, Crit Care Med. 2017 February; 45(2): 321–330

APPENDIX D: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

War Wounds: Debridement and Irrigation (CPG ID:31)

This CPG reviews indications for and the procedures associated with battle related wound debridement and irrigation, and associated initial wound management strategies for penetrating war wounds.

** Interim and Preliminary Update **

Final version is pending. For questions about this CPG, contact dha.jbsa.healthcare-ops.list.jts-pips@health.mil

SUMMARY OF CHANGES

- Inclusion of tetanus and antibiotic prophylaxis.
- Early identification and treatment of wounds at high risk for invasive fungal infection.
- Inclusion of antibiotic powder as an option for wound prophylaxis and contrasting effect of negative pressure wound therapy on local antibiotic delivery in wounds using polymethyl methacrylate (PMMA) antibiotic beads and antibiotic powder.
- Revision of section on a retained foreign object (RFO).

BACKGROUND

Wound debridement and irrigation (D&I) is the most frequently performed surgical procedure in the combat theater.[1] Given the power of war munitions, prompt removal of nonviable tissue, debris, blood and bacteria is imperative to prevent local and systemic complications associated with such a wound.[2] Appendix A outlines the injury patterns and resulting physiology from weapons of war. Care must be given to ensure all nonviable tissue is removed, while at the same time preserving as much soft tissue as possible for reconstructive surgery at higher echelons of care.[3] Balancing these two competing factors often necessitates serial D&I. While there are a variety of different therapeutic options of varying efficacy, no one approach is perfect for all situations.

***NOTE**: Related CPGs: Invasive Fungal Infection in War Wounds, Acute Traumatic Wound Management in the Prolonged Field Care Setting, Infection Prevention in Combat-Related Injuries. CPGs can be viewed/downloaded from https://jts.health.mil/index.cfm/PI_CPGs/cpgs.*

EVALUATION AND TREATMENT

IMMEDIATE PROPHYLACTIC MEASURES

U.S. Service Members should routinely receive tetanus toxoid and single-dose IV antibiotic (typically Ancef) for war wounds. Host nation patients or those with unclear vaccination histories should receive toxoid, Ancef and tetanus immune globulin. (Refer to *Infection Prevention in Combat-Related Injuries CPG*).

DEBRIDEMENT

Thorough inspection of the wounds with liberal use of surgical enlargement (i.e. wide surgical exposure) is necessary to inspect all levels of tissue, including examination of fascial planes and the integrity of neurovascular structures. This may require extension to outside the zone of trauma. When extending the wound into healthy tissue, consideration should be given to how this could potentially affect future reconstructive or closure options.[4] In general, extremity wounds should be extended in a longitudinal manner (parallel with the bone) and truncal wounds should be extended along Langer's lines (see figure below). Wound configuration and need for additional vascular exposure must be considered and this may at times violate all of the above precepts.

Figure 1. Langer Lines

Source: Integrated Activities in Primary Care – Minor Surgery in Family Medicine. IntechOpen. 11 May 2016

It is critical that the wartime surgeon has an appreciation for the phenomenon of wound evolution and weapon ballistics. Military assault rifles and proximity blasts cause large areas of cavitation because the kinetic energy transfer exceeds the area of tissue destruction by the projectile.[5] Such wounds are known to appear viable or questionably viable but progress to necrosis over the subsequent 24-72 hours from microvascular thrombosis and ischemia. Blast wounds are heavily contaminated with environmental debris and, sometimes, foreign tissue from other blast victims. Furthermore, regional vascular injury, tourniquet use, hemorrhagic shock, and persistent critical illness also diminish the capacity for wound healing and lead to disappointing evolution of the war wound. Therefore, avoid closure of wounds after the first washout or within the first 48 hours. Premature wound closure causes severe morbidity from necrotizing infection, often invisible on external exam until late in the process. Appendix A outlines the injury patterns and resulting physiology from weapons of war.

Surgeons should anticipate the need to frequently re-inspect and perform serial D&I on extensive soft tissue wounds.[3] While there is not a strict guideline defining the time sequence of repeat D&I, a general rule is frequent inspections in the operating room (every 24 hours) until all non-viable tissue has been debrided while all other tissues are confidently viable. This prevents overly aggressive removal of questionably viable tissue at the early debridements while still aggressively addressing progression of necrosis. Once such wounds have stabilized with absence of nonviable tissue, inspections can be separated in time by 2 days or more until a final wound closure strategy is identified. Strategies include healing by secondary intent, delayed primary closure, split thickness skin graft, or tissue transfer. Patient movement decisions should be adapted to the requirements of surgical management – not the converse. When possible, ensure that a planned D&I is done within 24 hours prior to patient movement

to ensure the receiving team has adequate time to assess and schedule follow-on wound care. In general, leave the wound open until arrival at the definitive care facility.

It is recognized that unstable blast injury patients with multiple fragmentation injuries over much of their bodies may not be able to undergo thorough debridement of all wounds at initial operation; this can be due to instability, lack of resources, lack of personnel, or urgency of transfer. It is therefore important that extent and adequacy of what debridement has been done is documented to guide further treatment at receiving facilities.

Sharp surgical debridement is the mainstay of care for war wounds; irrigation is an adjunct, but in no way replaces debridement for removal of non-viable tissue in wounds. Meticulous sharp debridement using a scalpel and/or scissors should be a starting point for most wartime wounds. Assurance of hemostasis and removal of all nonviable skin, fat, fascia, muscle, and bone are essential to reduce the load of contamination and necrotic tissue prior to dressing application.[4]

The need for repeat serial inspection and wound debridement cannot be over-emphasized. Unstable blast injury patients with multiple fragmentation injuries may not receive thorough debridement of all wounds at initial operation due to resuscitation needs, lack of resources, lack of personnel, or urgency of transfer. Always document the extent and adequacy of debridement performed as well as debridements still required. When receiving a patient from a forward role of care within the first 24 hours of injury, urgent operative re-exploration of all wounds is a best practice. Pre-operative CT scan is an important adjunct to identify areas of radiopaque debris or soft tissue air. These serve as a signal for areas of occult injury, residual contamination or necrosis that guides the next debridement.

IRRIGATION

There are several acceptable devices available for wound irrigation. Simple bulb syringe irrigation and gravity irrigation are the preferred methods. Large bore gravity-fed tubing is favored for irrigations requiring large fluid volumes, such as those associated with contaminated open fractures. Cystoscopy tubing connected to a 3 liter saline bag is ideal for gravity irrigation of large or multiple wounds. Pulsatile jet lavage irrigation using a battery powered system is not associated with improved outcomes but increases expense, weight, and space.[6,7] All methods of wound irrigation are adjuncts and not substitutes to sharp surgical debridement.

The current recommendations for volume of irrigation are as follows:

- 1-3 liters for small volume wounds.
- 4-8 liters for moderate wounds.
- 9 or more liters for large wounds or wounds with evidence of heavy contamination.

This takes into account that bacterial loads drop logarithmically with increasing volumes of irrigation. Depending on the environment and medical logistics support, the volume of sterile fluids may not be available. Normal saline, sterile water and potable tap water all have comparable efficacy and safety as irrigation solutions.[8,9] The inclusion of irrigation fluid additives such as iodine, bacitracin or antibiotics is without proven benefit.[7]

WOUND DRESSINGS

While wet-to-dry dressings are a mainstay for the management of open traumatic wounds, negative pressure wound therapy (NPWT) has become the more common and frequently preferred method for large soft tissue wounds. The principals of wound care are cleanliness and micro debridement. Wet-to-dry dressings, when done properly, achieve both; dressings keep the wound moist and provide mechanical debridement when removed. If the wound is too wet, it will not debride. If the wound is too dry, then it will impede healing. Optimal wound care management with wet to dry dressing requires the dressing to be changed every 12-24 hours; more frequent dressings may be needed, depending on the wound's size, exudate burden, contamination, and vascularity. The use of either normal saline, sterile water, or potable water for the dressing are equally efficacious. This strategy for wet-to-dry dressings may need be adapted to a dry-to-wet dressing in a highly exudative/weeping wound. For highly contaminated wounds, the use of Dakin's solution has been suggested to decrease the rates of invasive fungal infections (IFI); however, the sodium hypochlorite may be toxic to macrophages, fibroblasts and neutrophils.[10,11]

NPWT with Reticulated Open Cell Foam (NPWT/ROCF), commonly referred to as the VAC (vacuum assisted closure therapy system) dressing, is a commonly used alternative to wet-to-dry dressings. NPWT dressing can be left in place up to 72 hours depending on the extent and acuity of the wound. Utilization of NPWT requires a hemostatic wound bed and absence of purulence. The VAC Therapy System comes with a default negative pressure setting of 125mmHg. For large wound volumes, the pressure setting can be increased and/or an additional suction pad may be placed and connected with a "Y" connector. NPWT may aggravate bleeding in wounds with challenging hemostasis or venous hypertension. Clotted blood visible through the plastic covering or high amounts of dark sanguineous output indicate a need to return to the OR for hemostasis. Foam should not come into physical contact with exposed vessels. Use of VAC therapy has been proven safe and stable for long range air evacuation transports.[12]

The use of NPWT offers several advantages over wet-to-dry dressings. NPWT allows for accurate measurement of fluid loss from the wounds, prevents fluid soilage on linens and gurneys, obviates the need for painful bedside dressing changes, and promotes granulation tissue. However, there are many pitfalls that must be avoided with the placement of NPWT. It is imperative in large or deep wounds that all the ROCF is in contact with the suction source. If a piece of sponge in the wound is isolated from suction, bacteria will grow from fluid stasis. This especially applies to amputations from blasts where cavities track between muscle groups. In the unanticipated event of prolonged care at a Role 2 location, NPWT can be improvised without needing to stock commercial VAC supplies. NPWT can be devised using any suction source, Kerlex roll gauze, a conduit like a nasogastric tube (with the blue sump port tied in a knot), and an occlusive dressing like Ioban. The improvised VAC technique is further described in the *JTS Acute Traumatic Wound Management in the Prolonged Field Care Setting CPG*.[9]

IFI CONSIDERATIONS

IFIs are opportunist infections which tend to occur at the far end on the spectrum of war wound severity. IFIs are so devastatingly morbid and lethal they have their own CPG (*Invasive Fungal Infections in War Wounds*). However, because there are clinical factors that can predict wounds at greatest risk for IFI and because the irrigation and dressings for these wounds should be managed differently from what has been mentioned above (using Dakin's solution), these differences will be highlighted here.

During the first debridement, assess patients for IFI risk factors:

- Dismounted blast injury
- Above knee immediate amputation
- Extensive perineal/genitourinary/rectal injury
- Massive transfusion of >20 units in the first 24 hours (or anticipation of 20 units)

If three of the above factors are present, switch irrigation to high-volume Dakin's solution and dressings should be wet-to-dry using Dakin's solution. Furthermore, because IFI also occurs with wounds not initially meeting the criteria listed above, additional criteria seen after subsequent debridement should also prompt the same change to Dakin's irrigation and dressings.

Look out for these additional IFI risk factors on subsequent inspections of wounds not previously considered at risk of IFI:

- Progression from below-knee to through-knee to above-knee amputation
- Recurrent necrosis following at least two consecutive debridements

(Refer to the *Invasive Fungal Infection in War Wounds CPG* for more discussion of steps taken at Roles 3, 4 and 5 for suspected IFI.)

EVACUATION CONSIDERATIONS

It is critical that the down-range surgeon be mindful of timing of D&I with casualty evacuation. To avoid extended periods without wound inspection due to fixed wing flight, a best practice is to anticipate movement and plan debridement within 24 hours of movement. Generally, large acute wounds will need inspection and D&I every 24 hours during the first few days after injury. Ideally, serial D&I should be completed by the same provider, and photo documentation of wounds obtained (in compliance with theater policy); however, the nature of patient evacuation may result in rapid transport from the point of injury to the Role 1, 2 and 3 in a compressed timeline. Most wounds should not be closed prior to arrival at a definitive care location. Providers receiving a patient with a closed wound should have a relatively low threshold to reopen a wound if there are any concerns for contamination or non-viable tissue having been left behind. This compulsive approach to combat soft tissue injuries will decrease the likelihood that a wound will worsen and result in adverse patient outcomes.

CLOSURE

War wounds are contaminated and frequently result from high velocity injuries. Unless they occur from mechanisms other than battle injury, war wounds should not be treated with primary wound closure in the deployed setting. Though no hard rules exist for the closure of battle injuries, wartime experience demonstrates four broad categories of wound outcome:

1. Healing by secondary intention
2. Delayed primary closure with or without drain placement
3. Split thickness skin graft over local soft tissue
4. Tissue transfer with subsequent split thickness skin graft

Which of these four closure strategies is best suited for any given wartime soft tissue injury is left to the discretion of the surgical team.

ANTIBIOTIC BEADS

Placement of antibiotic impregnated PMMA can be used as an adjunct to D&I to deliver increased local antibiotic concentrations while minimizing the associated side effects of high systemic loads of these antibiotics. Indications include contamination with open fractures and traumatic amputations, treatment of established osteomyelitis, and dead space management with associated soft tissue defect. Animal models demonstrate a PMMA bead pouch is more effective without NPWT because the antibiotic remains in the wound without collecting in the vacuum canister.[13] The PMMA beads are usually prepared on a suture or wire and laid within the wound and covered with a semipermeable membrane, forming a bead pouch. Typically reserved for Role 3 and 4 use, a PMMA bead pouch may be used in conjunction with NPWT. It may be helpful to place the antibiotic beads in the deep portion of the wound and not in direct contact with the reticulated open cell foam to allow stasis of antibiotics concentrations in the wound. The choice of antibiotic should be directed by the local antibiogram. Common antibiotics include heat stable powder formulations of tobramycin, vancomycin, imipenem, and colistin. Recent evidence also supports prefabricating and sterilely packaging PMMA beads for subsequent use, allowing for bead use in a multi-casualty/time constrained setting. The efficacy of this adjunct is supported by several small studies and case series which, in aggregate, suggest this can lead to a 10% or greater absolute decrease in wound infections.[14] Further research is needed on its use in combat trauma patients. Recent epidemiologic studies by the Trauma Infectious Disease Outcomes Study Group showed an increased rate of osteomyelitis when PMMA antibiotic beads were used.[15-17] These results should be viewed cautiously as they did not control for confounding factors (such as selection bias that the beads were used or patients at a higher baseline risk of developing osteomyelitis).

ANTIBIOTIC POWDER

There is a groundswell of interest in use of topical antibiotic powders (TAP) for prophylaxis in wounds with contaminated fractures. Recent large animal studies comparing TAP and antibiotic PMMA beads in wounds treated with NPWT show that TAP achieves higher sustained wound concentrations and is more effective at curbing bacterial growth.[18] Analysis of the collected NPWT drainage indicates about half of the antibiotic is removed with suction, indicating that the amount of powder can be increased when used in conjunction with NPWT. A recent prospective randomized multicenter trial of 980 patients with tibial plateau or pilon fractures at high risk of infection showed a 33% relative risk reduction in deep surgical site infection (SSI) using 1gm of topical vancomycin powder immediately before wound closure. Analysis of the infecting organisms showed that the difference in overall infection rate was directly attributable to gram positive sensitivity to vancomycin, with a 50% relative risk reduction in gram positive deep SSI and no effect on gram negative deep SSI. Fractures without soft tissue coverage or with combined vascular injuries were excluded from enrollment.[19] There is insufficient data at this time to advocate widespread antibiotic powder use during serial debridement of war wounds with concomitant fracture.

RFO PREVENTION

An RFO event refers to an iatrogenic event in which a sponge or surgical instrument is deliberately or unintentionally left behind while the wound proceeds to definitive management. Both surgical and traumatic open wounds are at risk for RFOs. Several features unique to the deployed environment place patients at increased risk of this complication. Among these risk factors are multiple surgical teams performing procedures on multiple wounds simultaneously, multiple surgeons performing procedures at different times, instrument and sponge counts being omitted in hemodynamically unstable patients, patients undergoing care at multiple different treatment facilities, and minimal documentation on operative records. The most obvious example of this would be definitive closure of the abdomen with a retained lap sponge. A less obvious vignette would be deliberate temporary hemostatic closure of a thigh compartment over Combat Gauze unrecognized by subsequent surgical teams at higher roles of care. Even with a slower operational tempo, RFO events continue to happen as these are two examples of true events occurring in Iraq and Afghanistan within the last 5 years. The deployed environment is high risk for RFO events because of the frequency of severe injuries requiring staged operations with temporary packing for hemostasis, multiple locations with multiple surgical teams, limited OR support for sponge and instrument counts during exigent circumstances, and communication challenges during patient hand-offs between roles of care. Strategies must be undertaken to mitigate these risks.

Best practices include:

1. The medical record must reflect any material that has been purposefully left in the wound.

2. Physician-to-physician communication (preferably surgeon-to-surgeon) should occur if foreign bodies remain in the wound.

3. There should be a low threshold to obtain radiographs to confirm removal of all foreign bodies. This is particularly important for cases in which a sponge and instrument count were omitted due to hemodynamic instability, discrepancies during the closing or final sponge an instrument count, or when a wound is being closed by a different surgeon at a subsequent treatment facility. Ideally, the images should be reviewed by both the surgeon and radiologist before closing the wound and leaving the operating room. The use of radiofrequency-labeled sponges and detectors is an adjunct to improve detection of retained sponges, but does not remove the need to use x-rays to definitively clear a cavity of sponges. Not only is it possible that a forward role of care used non-RFID lap sponges, but combat gauze can be used to control challenging intracavitary bleeding and will only be detected on x-ray.

FACIAL WOUNDS

While traumatic facial wounds are treated in a similar fashion to wounds in other areas of the body, some aspects of facial wound management deserve special attention. Maxillofacial wounds sustained in combat typically involve both soft tissue and other structures including bone, teeth, cartilage, mucosa-lined structures (sinuses, mouth, etc.), eyes and the cranial vault. As such, maxillofacial wound management may be more complicated than soft tissue wounds in other parts of the body, and may warrant multidisciplinary care. Facial wounds and their management can significantly impact the patient's airway, vision, and ability to speak and eat. Severe injuries to the midface or mandible may necessitate immediate airway control.

The robust, redundant blood supply of the facial region promotes healing and reduces the incidence of wound infection compared to the trunk and extremities. As with other wounds, the first step in facial wound management involves excellent hemostasis, profuse irrigation, and meticulous debridement. All clearly non-viable tissue must be sharply excised. Threatened but potentially viable tissue should be maintained – especially around the eyes. Given the rich vascular supply of this region, it is better to conserve as much tissue as possible during the initial debridement as opposed to aggressive, wide debridement. Primary closure, while contraindicated in wounds in other areas of the body, is acceptable for many wounds of the face. Consider use of fast-absorbing sutures in any patient with unreliable follow up. Large areas of missing tissue may be covered temporarily with dressings, taking care to keep the tissues moist. Consider local or regional flaps in the acute phase when there is exposed bone or cartilage. In high velocity injuries, the surgeon should conserve as much tissue as possible during the first surgery and allow the wound to demarcate. After several days of wound care, the resulting defect can be repaired using a musculocutaneous flap.[20] Most importantly, the surgeon must cover all exposed bone and cartilage with vascularized tissue and an appropriate antibiotic ointment to prevent infections in these structures.

The use of NPWT/ROCF has not been well documented in the treatment of facial wounds but may be appropriate in some situations where there is extensive tissue loss. If a cerebrospinal fluid leak is suspected, this should be avoided. Foreign bodies, along with damaged bone and cartilage lacking periosteum and perichondrium, should be removed while carefully preserving the remaining viable tissues to the greatest extent possible. Antibiotics should be used for all facial wounds associated with sinus, nasopharyngeal or oropharyngeal injuries. Injuries to cartilaginous structures (i.e. ears, nose) are especially susceptible to Pseudomonas aeruginosa and Staphylococcus aureus infections. (Refer to the *Infection Prevention in Combat-Related Injuries CPG*.)

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

All patients with wounds requiring debridement and irrigation within 1 day of injury.

INTENT (EXPECTED OUTCOMES)

- Combat wounds are treated with sharp surgical debridement, augmented by irrigation, at the first surgical role of care, or reason for delay documented.
- Combat wounds remain open after initial operation (excluding face and scalp wounds).

PERFORMANCE/ADHERENCE MEASURES

- Number and percentage of patients in population of interest who received sharp debridement of combat wounds at the first surgical role of care.
- Number and percentage of patients in the population of interest who have wounds left open at the initial operation (excluding face and scalp wounds).

DATA SOURCES

- Patient Record
- Department of Defense Trauma Registry

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Chief and the JTS PI Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local level with this CPG.

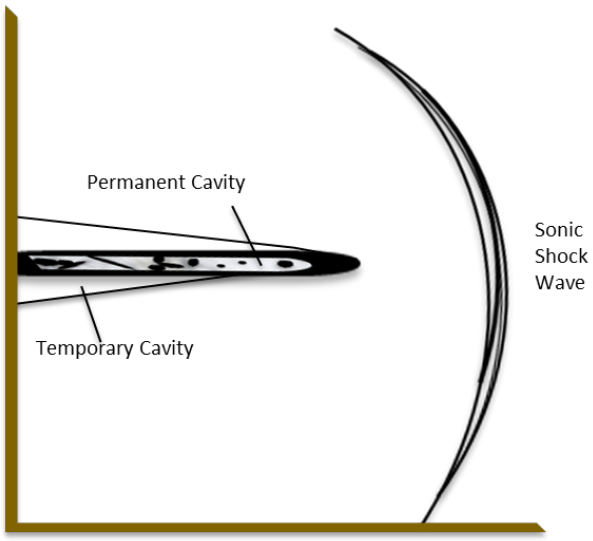
APPENDIX A : WEAPON EFFECTS

Military munitions and firearms produce injuries not commonly seen in civilian trauma. Weapon types can be roughly divided into two major subtypes: small arms fire and explosive munitions. Small arms fire is typically from hand guns and assault rifles.[1]

When a small arms projectile hits tissue, it produces two types of injuries: a permanent cavity and a temporary cavity. The permanent cavity is the tissue destroyed by the actual pathway of the projectile. Military rounds are designed to turn, or yaw, upon contacting tissue. As the bullet turns, the permanent cavity size increases. This is evidenced by small entry wounds and large exit wounds. A second, temporary cavity occurs from a pressure wave created by the high-velocity round. Elastic, and inelastic tissue, is put under stress which manifests as delayed necrosis and is one of the reasons we do not advocate for wound closure following the initial debridement. The degree of damage is proportional to a projectile's kinetic energy and more specifically its velocity (Kinetic Energy = ½ (Mass) x Velocity). Particles distributed by blast explosions also create permanent and temporary cavities.

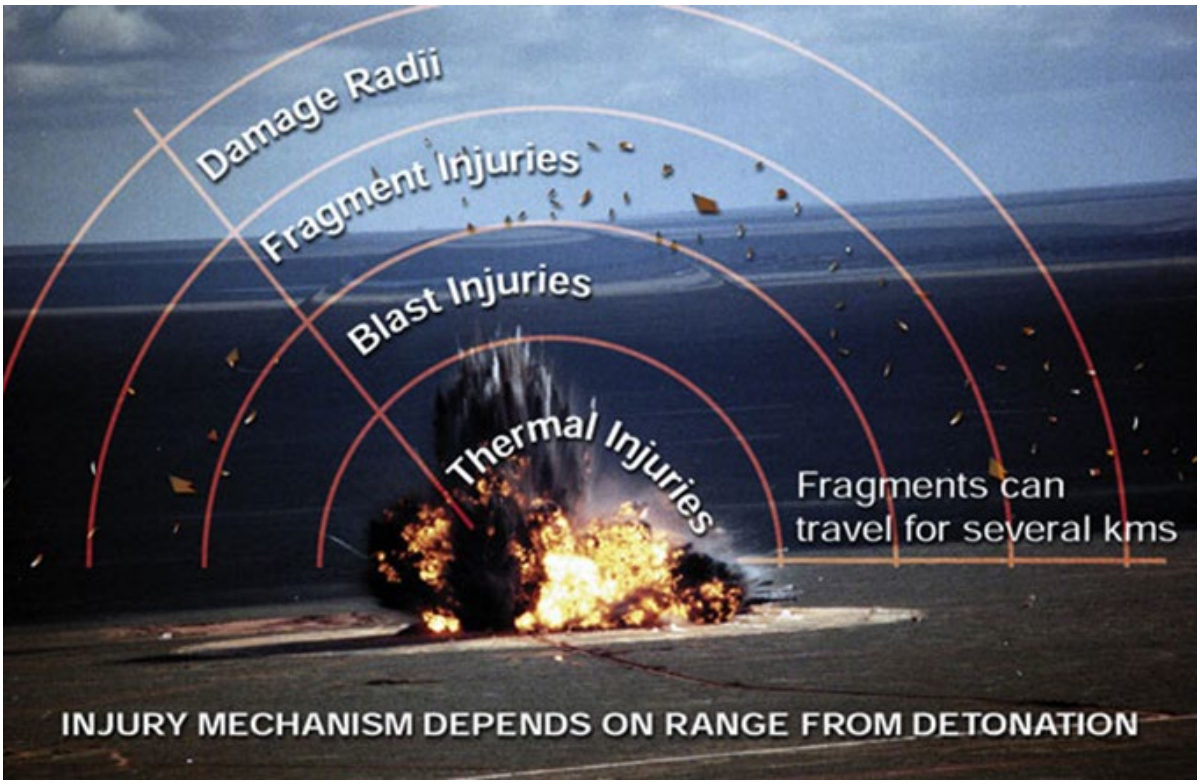
Figure A-1. Two areas of projectile-tissue interaction



Explosive munitions injure through four major mechanisms. The number of mechanisms a person is exposed to depends on their distance from the explosion, with persons closer to blasts being exposed to more mechanisms of injury. (See Figure 2 below.) Primary blast injuries occur from a pressure wave known as a blast wave. The blast wave can sheer off tissue, damage solid organs, and damage hollow viscus injuries from pressure changes in the air contained within the organs. These injuries may manifest several days after the blast and are typically discovered on serial examinations of the injured patient. Secondary blast injuries are penetrating injuries which result from particles contained within the munition or from debris from the surrounding environment distributed by the blast. Tertiary blast injuries comprise two subtypes of injury. The first is a negative pressure wave called a blast wind which follows the positive pressure of a blast wave. Similar injuries are produced by both blast wind and blast waves. The second subtype of injury is blunt trauma resulting from large objects being projected into a body, or a person's body being projected into the surrounding environment, like a wall or the ground. When a blast hits a vehicle, occupants are susceptible to being injured by sequential pressure waves as they reflect around the inside of the vehicle. Quaternary blast injuries also comprise two major subtypes. The first subtype is burn injuries, which are treated as outlined in the JTS Burn Care Clinical

Practice Guideline. The second are CBRNE injuries (Chemical, Biological, Radiological, Nuclear, and Environmental Injuries) and are managed as outlined in CBRNE guidelines.

Figure A-2. Four mechanisms of blast injury



Virtually every organ is susceptible to injury from blast explosions and many of these injuries, particularly hollow viscus injuries and soft tissue necrosis, present in a delayed format, necessitating serial exams and clinical awareness.

APPENDIX B: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Wartime Thoracic Injury (CPG ID:74)

The goal of this CPG is to provide guidance on the diagnosis, initial treatment, and surgical management of thoracic injuries in the deployed or operational environment.

BACKGROUND

Thoracic injuries are present in 12 to 50% of civilian trauma patients.[1] Over 90% of these civilian injuries are due to a blunt mechanism, and less than 10% require surgical intervention.[2] In contrast, significant thoracic trauma is present in only 10% of combat-injured patients, but the great majority of cases are associated with penetrating mechanism.[3,4] The most common thoracic injuries are pneumothorax, pulmonary contusion, and chest wall trauma, whereas injuries to the lung or great vessels have the highest mortality rate.[3] Tube thoracostomy is indicated as an initial diagnostic and therapeutic intervention for the majority of patients with thoracic trauma. For more severe injuries, thoracotomy (primarily anterolateral), sternotomy, or other surgical approach may be indicated on an emergency basis.

ROLES OF CARE AND THORACIC INJURY

Each role of care has unique approaches to the management of thoracic trauma:

- **Role 1:** The focus is treatment or stabilization of immediate life-threatening thoracic injuries, such as airway obstruction, and tension pneumothorax. Follow the Tactical Combat Casualty Care guidelines for treatment of chest trauma.[5]
- **Role 2:** Care is focused on resuscitation and damage control surgical procedures. Tube thoracostomy placement is a critical diagnostic and therapeutic intervention. Anterolateral thoracotomy or sternotomy may be required for acutely bleeding patients.
- **Role 3:** Definitive surgical treatment should be attempted for most injuries, with the possible exception of complex tracheobronchial or great vessel injuries.
- **Role 4:** Definitive therapy.

Table 1. Summary Recommendations for the Management of Thoracic Injuries

Summary Recommendations for the Management of Thoracic Injuries
1. Tube thoracostomy is indicated as the initial therapeutic intervention for most patients with penetrating thoracic trauma, and for any patient with suspected significant pneumothorax/hemothorax. At the Role 1 level, needle decompression is indicated for suspected tension pneumothorax.
2. Intrapericardial cardiac or great vessel injury should be suspected in any patient with penetrating thoracic or upper abdominal trauma, and generally can be diagnosed using ultrasonography or surgical pericardial window.
3. Left anterolateral thoracotomy (resuscitative thoracotomy) is the incision of choice in any penetrating thoracic trauma patient who is in extremis or profoundly unstable, who loses vital signs immediately before arrival, or has an observed loss of vital signs. This should be combined with right tube thoracostomy or extension of the thoracotomy to a clamshell if a mediastinal or right chest injury is suspected.
4. For a patient with palpable pulses and penetrating chest wound with hemopericardium, sternotomy is usually the preferred initial incision. If the diagnosis of hemopericardium is uncertain, sternotomy should be preceded by subxiphoid pericardial window.
5. The management of suspected subclavian vascular injuries is complex and technically demanding, and may require a combination of sternotomy, anterior thoracotomy, and supra/infraclavicular incisions.
6. For patients with suspected esophageal perforation, tracheobronchial injury, or blunt great vessel injury, the initial focus should be on stabilization, temporary control and wide drainage, rather than definitive repair.
7. For unstable patients with significant combined thoracic and abdominal trauma, exploratory laparotomy should be combined with bilateral tube thoracostomy and trans-diaphragmatic pericardial window to allow for a complete assessment and treatment of major injury.
8. Patients undergoing surgical intervention for acute thoracic trauma should be approached in the supine position and prepped for multiple potential incisions with a low threshold for additional incisional exposure to control life-threatening injuries. Posterolateral thoracotomy is rarely indicated in the acute trauma setting.
9. Observation of a small pneumothorax is not appropriate for any patient undergoing prolonged transport. In cases where clinical or radiographic findings are equivocal, clinicians should err on the side of tube thoracostomy prior to transport.
10. In rare circumstances, the use of Extra-Corporeal Membrane Oxygenation may be needed in the setting of a complex thoracic injury resulting in severe hypoxia, hypercapnia, or heart failure. For ECMO referrals 24/7, contact (210) 916-ECMO/DSN (312) 429-ECMO (leave message if not answered immediately); alternate contact is SAMMC operator at (210) 916-2500/DSN (312) 429-2500.

DIAGNOSIS OF THORACIC INJURIES

As with all trauma patients, the evaluation of a patient with thoracic trauma begins with a determination of airway patency, adequacy of breathing, hemodynamic stability, and neurological status. Where available, ultrasound and chest X-ray are useful diagnostic adjuncts.

PNEUMOTHORAX, HEMOTHORAX

1. In a patient with thoracic trauma and a clinically patent airway who has rapid, inadequate, or labored respirations, the diagnosis of pneumothorax must be assumed until proven otherwise.

2. Absent or markedly decreased breath sounds in a patient with known thoracic trauma indicate the need for intervention without additional diagnostic testing. In addition to treating pneumothorax or hemothorax when present, tube thoracostomy may be diagnostic of these conditions based on a rush of air or blood after tube placement.

3. In a patient with normal hemodynamics and adequate oxygenation and ventilation, it is reasonable to confirm a pneumothorax by chest X-ray or ultrasound prior to tube thoracostomy.

TENSION PNEUMOTHORAX

1. Signs and symptoms of tension pneumothorax include severe or progressive shortness of breath or hemodynamic compromise in the setting of chest trauma.

2. Differentiating between a simple pneumothorax and a tension pneumothorax is based on the presence of hemodynamic effects (hypotension and decreased perfusion) in the latter condition. While a patient with thoracic trauma and a pneumothorax may present with multiple injuries and an alternate explanation for hypotension (such as cardiac tamponade, intraabdominal bleeding, or hemothorax), immediate needle or tube thoracostomy is the necessary first step in this scenario. In the case of a tension pneumothorax, this maneuver should have both diagnostic and therapeutic benefit.

3. Patients who are hypovolemic are more susceptible to the hemodynamic effects of tension pneumothorax.

OPEN PNEUMOTHORAX (SUCKING CHEST WOUND)

Open pneumothorax occurs when a defect in the chest wall is sufficiently large to impair effective air exchange (air will preferentially pass through the defect if larger than 2/3 the tracheal diameter). In the case of an open pneumothorax due to a large chest wall defect, the diagnosis will be clinically obvious on physical examination.

RIB FRACTURES, FLAIL CHEST

1. Rib fractures are a clinical diagnosis based on chest wall pain and point tenderness (with or without crepitus) in the setting of blunt or penetrating chest wall trauma.

2. Maintain a high index of suspicion for associated injuries (pulmonary contusion, pneumothorax, splenic or liver laceration, etc.).

3. Rib fractures are associated with pneumothorax, hemothorax, solid abdominal organ injury, and thoracic great vessel injury. Patients must be assessed for these associated injuries.

4. Flail chest may be diagnosed clinically by gross chest wall instability or paradoxical chest wall movement with respiration. Practically, the differentiation between rib fractures alone and a flail

segment is not important, as the initial management is the same for both conditions. The morbidity of this type of injury is determined by the underlying pulmonary contusion which may impair gas exchange and the consequences of low lung volumes due to pain.

PULMONARY CONTUSION

1. Pulmonary contusion is most common with blunt trauma or blast injury.

2. Patients with pulmonary contusion may present with respiratory distress and reduced breath sounds on the injured side. Often, symptoms may not manifest immediately after injury. Chest X-ray may show patchy opacity(s). However, lung contusion is primarily a clinical diagnosis.

3. It can be difficult to differentiate between pulmonary contusion and pneumothorax when imaging is not available. In this scenario, if the patient is significantly symptomatic and does not improve with initial pain management, one must assume that pneumothorax is present, and tube or needle thoracostomy is indicated (particularly prior to transport).

CARDIAC TAMPONADE

1. For low-velocity penetrating injuries, the possibility of intra-pericardial cardiac or great vessel injury should be considered when there is penetrating trauma in the “box” defined by the space inferior to the clavicles, superior to the costal margin and medial to the mid-clavicular line.

2. With high velocity gunshot wounds and multiple penetrating blast fragment wounds, intra-pericardial damage is possible with any penetrating injury to the chest or upper abdomen.

3. Ultrasound assessment is a rapid, simple, and widely available tool to assess for significant hemopericardium, which indicates intra-pericardial injury in this setting. When a hemopericardium and hypotension co-exist in a patient with significant trauma (of any mechanism), no further diagnostic evaluation is indicated. However a negative pericardial ultrasound in penetrating chest trauma does not definitively rule out cardiac injury or pericardial blood as sometimes blood can drain from the pericardium into either the right or left chest if there is a hole in the pleural pericardium.

4. Classic physical exam findings of tamponade (distended neck veins, muffled heart sounds) are not reliable.

5. In a hypotensive patient undergoing exploratory laparotomy for penetrating abdominal injury, a trans-diaphragmatic pericardial window is a rapid means to evaluate for hemopericardium/tamponade.

GREAT VESSEL INJURY

1. Most combat-related great vessel injuries are fatal at the point of injury.

2. In some cases, particularly after major blunt trauma, a patient may present with a contained great vessel injury associated with a mediastinal hematoma. Although a widened mediastinum on plain chest X-ray may be suggestive of this injury, computed tomographic angiography is necessary for

diagnosis. Other X-ray findings suggestive of great vessel injury include apical capping, tracheal deviation, wide paratracheal stripe, and downward deviation of the left main bronchus.

3. If a contained great vessel injury is suspected (mediastinal hematoma), such an injury is unlikely to acutely cause hypotension, and other causes of bleeding and hypotension should be sought.

ESOPHAGEAL PERFORATION

1. Esophageal perforation is a rare injury since the esophagus is protected in the posterior mediastinum. It may be suspected due to wound trajectory, and occurs most often in association with other penetrating injuries.

2. The diagnosis is commonly delayed and there should be high index of suspicion for this rare injury depending on mechanism of injury and fragment trajectories. The diagnosis may be suspected or confirmed after placement of a tube thoracostomy for a pleural effusion/hemothorax. Contents of the drainage may contain gastrointestinal contents.

3. Endoscopy, esophagram and/or computed tomographic (CT) scan can confirm the diagnosis.[6]

TRACHEOBRONCHIAL INJURIES

1. Penetrating proximal thoracic tracheobronchial injuries are rarely encountered due to their proximity to the great vessels and heart and subsequent lethality.

2. Diagnosis requires a high index of suspicion. The most common diagnostic signs are subcutaneous emphysema, pneumothorax and hemoptysis. Hoarseness and dysphonia are also common symptoms. Respiratory failure, the presence of a pneumothorax on chest X-ray, or a large air leak after tube thoracostomy are typical but non-specific findings.

3. If there is concern for a tracheobronchial injury, bronchoscopy should be performed with documentation of injury location and severity of injury.[7] The most common locations are in the distal trachea and proximal mainstem bronchi (within 2cm of the carina).

DIAPHRAGMATIC INJURIES

1. Diaphragm injuries commonly occur with high energy blunt trauma or penetrating thoracoabdominal injuries. Diaphragm injury should be considered in any thoracoabdominal penetrating trauma.

2. Auscultation of bowel sounds in the chest are highly suggestive of diaphragm injury but are rarely identified. On ultrasound exam, bowel may be seen in the chest. If there is concern for diaphragm injury, placement of a nasogastric tube with subsequent chest X-ray may confirm the diagnosis.

3. Small diaphragm injuries typically go undetected until direct examination of the diaphragm at the time of surgery (laparotomy, laparoscopy, thoracotomy, thoracoscopy). A high index of suspicion for diaphragm injury should be maintained for penetrating wounds to the left and right upper quadrant.

4. Diaphragm injuries may allow blood from the abdomen to be drawn into the negative pressure region of the chest. In this case, abdominal bleeding may present as a hemothorax.

INITIAL MANAGEMENT FOR THORACIC TRAUMA

The most important early priority in the treatment of a patient with thoracic trauma is assessment and treatment for injuries that may be immediately life-threatening (listed below). Tube thoracostomy is often indicated in a severely injured thoracic trauma patient, and will generally provide useful clinical information (and potential treatment) regardless of diagnosis.

TENSION PNEUMOTHORAX

1. Clinical suspicion of tension pneumothorax requires rapid treatment, either with needle decompression and subsequent tube thoracostomy, or with immediate tube thoracostomy. The choice between these two alternatives depends on the immediate availability of thoracostomy supplies, the patient's condition, and the experience of the person performing the procedure.

2. Needle decompression should be performed with a large bore (14 gauge or larger) 3.25in/8cm catheter in the 4th or 5th intercostal space, anterior axillary line. The alternate needle decompression site is the 2nd intercostal space at the mid-clavicular line (this is the primary site in children). Ensure dedicated needle decompression catheters are available with all emergency medical supplies; shorter (5cm) catheters used for venous access should be avoided as these will rarely penetrate the thoracic cavity and thus be ineffective.

3. Needle decompression alone is insufficient treatment for a pneumothorax and certainly ineffective for hemothorax and should in most cases be followed by placement of a tube thoracostomy as soon as feasible and safe. For stable patients who have undergone needle thoracostomy, evaluation with ultrasound or chest X-ray to assess the need for chest tube placement is appropriate.

4. If tube thoracostomy placement is delayed, providers should be prepared to repeat needle decompression as needed. Failure to improve after two needle decompressions most likely indicates an alternative diagnosis to pneumothorax (e.g., hemothorax, pulmonary contusion, and diaphragm injury).

5. Tube thoracostomy is performed using blunt/open technique, as described in Appendix A: Specific Thoracic Procedures.

OPEN PNEUMOTHORAX

Initial management with placement of a vented chest seal is reasonable until a tube thoracostomy can be performed.

MASSIVE HEMOTHORAX

1. The return of blood under pressure or a large volume of blood after tube thoracostomy indicates significant intra-thoracic injury.

2. Parenchymal lung injuries are the most common source of hemothorax, but massive hemothorax is likely due to a chest wall vascular injury, hilar pulmonary injury, or great vessel/cardiac injury.

3. With the immediate return of 1,500ml of blood after tube thoracostomy, thoracotomy is indicated. When the initial blood loss is below 1,500mL but significant bleeding continues (more than 200-250ml/hr and/or ongoing transfusion requirements), thoracotomy is also indicated.

4. In a patient with hemothorax due to penetrating injury and loss (or impending loss) of vital signs during or immediately prior to arrival, emergency resuscitative thoracotomy is indicated. (See the JTS Emergency Resuscitative Thoracotomy CPG.[8])

5. All patients with massive hemothorax will require damage control resuscitation and massive blood product transfusion (as outlined in respective CPGs).

6. Anterolateral thoracotomy is the best approach for massive hemothorax in an acute trauma patient. Although a posterolateral thoracotomy (ideally with lung isolation) may provide more optimal exposure, it presents limitations if additional incisional exposure is needed, may place the contralateral lung at risk for aspiration, and requires positioning maneuvers that may be challenging in a bleeding, acutely injured patient.

7. If after ipsilateral anterolateral thoracotomy, an intra-pericardial injury is encountered, conversion to a clamshell (bilateral thoracosternotomy) incision (described below) is indicated.

8. If a proximal left subclavian injury is encountered after left anterolateral thoracotomy, conversion to a trapdoor incision (described below) is an option to improve exposure.

9. In patients with penetrating trauma to the torso, a high suspicion must be maintained for bleeding in the other body cavities (opposite chest or abdomen).

10. Autotransfusion of shed pleural blood using a chest tube collection system and autotransfusion accessory can be considered.[9]

SUSPECTED CARDIAC OR GREAT VESSEL INJURY

1. Cardiac tamponade due to combat trauma requires immediate surgical intervention.

2. Fluid resuscitation may temporarily stabilize a patient in tamponade.

3. Pericardiocentesis (ultrasound guided, if available) combined with blood transfusion may help temporize a patient until arrival to a surgical capability,[10] recognizing that blood re-accumulation is likely.

4. Patients with suspected isolated great vessel injury (contained mediastinal hematoma) should receive pain control. If hemodynamics allow, this should be followed by a short-acting beta blocker (e.g., esmolol drip) to prevent tachycardia and hypotension.

RIB FRACTURES, FLAIL CHEST

1. In the absence of associated massive or ongoing bleeding into the pleural space, there is no role for surgical intervention for blunt chest wall injury. The major clinical significance of blunt chest wall injury in most cases is the potential for associated contusion of the underlying lung, which can have a major detriment on oxygenation and pulmonary status.

2. If physical exam or chest X-ray suggests the possibility of pneumothorax or hemothorax, immediate tube thoracostomy is indicated. In cases where clinical or radiographic findings are equivocal, clinicians should err on the side of tube thoracostomy prior to transport.

3. The treatment of rib fractures and flail chest includes pain control, close monitoring, oxygenation and ventilatory support as needed. Consider local and regional anesthetics in addition to systemic pain medications.

THORACIC TRACHEOBRONCHIAL INJURY

1. Initial management is aimed at ensuring adequate oxygenation and ventilation.

2. Tube thoracostomy is an important early intervention. If negative pressure suction through a tube thoracostomy worsens respiratory function due to a large air leak, the tube should be taken off of suction and placed to water seal. An alternative is connecting the chest tube to a one-way Heimlich valve.

3. If one chest tube does not re-inflate the lung, then a second chest tube should be placed.

4. Advancing an endotracheal tube into the right mainstem bronchus may help manage a significant tidal volume loss from left-sided injuries.

5. Other maneuvers, when available, include the use of bronchial blockers or double lumen endotracheal tube.

EXTRA CORPOREAL MEMBRANE OXYGENATION (ECMO)

1. ECMO may allow oxygenation for problematic injuries, and the DoD ECMO team should be contacted early if this is considered. For ECMO referrals 24/7 contact: (210) 916-ECMO/DSN (312) 429-ECMO (leave message if not answered immediately); alternate contact SAMMC operator at (210) 916-2500/DSN (312) 429-2500. DoD ECMO team members can also be reached by email at: usarmy.jbsa.medcom-bamc.list.ecmo@health.mil.

2. For specific ECMO indications, refer to the JTS Acute Respiratory Failure CPG.[11]

SURGICAL MANAGEMENT OF THORACIC TRAUMA

1. A patient with thoracic trauma for whom acute surgical intervention is planned has a life-threatening injury by definition. Therefore, the patient should be positioned to maximize options for necessary interventions: supine with arms out, prepped from chin to knees and chest to elbows. Large-bore access (IV, IO, or central venous) should be in place, and the airway secured with a cuffed endotracheal tube.

2. For a patient with penetrating thoracic trauma who is in extremis or who is profoundly unstable, left anterolateral thoracotomy is the incision of choice and should be combined with right tube thoracostomy. This incision can be extended across the midline (as a “clamshell” incision) for suspected intra-pericardial injury or right pleural space bleeding.

3. For a patient with palpable pulses and penetrating chest wound with hemopericardium, sternotomy is usually the preferred initial incision. If the diagnosis of hemopericardium is uncertain (ultrasound is unavailable or equivocal but there is a high clinical suspicion for cardiac injury), sternotomy should be preceded by subxiphoid pericardial window.

4. The management of subclavian vascular injuries is challenging. For suspected proximal left subclavian arterial injury, left anterior thoracotomy in the third interspace is a safe initial incision for proximal control. Proximal control of the right subclavian artery is best achieved via median sternotomy. Intravascular balloon

occlusion is an additional option to obtain proximal control of injuries to the great vessels. Refer to the JTS Vascular Injury CPG for further details.[12]

5. For repair of a subclavian artery injury after proximal control, the left or right proximal to mid-subclavian artery can be exposed via a supraclavicular incision. An infraclavicular incision provides exposure to the more distal subclavian artery and the subclavian vein. For more complex subclavian vascular injuries, a trapdoor incision will provide maximal exposure.

6. Lung parenchymal injuries should be resected in a non-anatomic fashion if possible. Anatomic resections should be performed only if the entire lobe has been damaged and is not salvageable. Trauma pneumonectomy should only be performed with non-salvageable hilar injuries and is associated with an extremely high mortality.

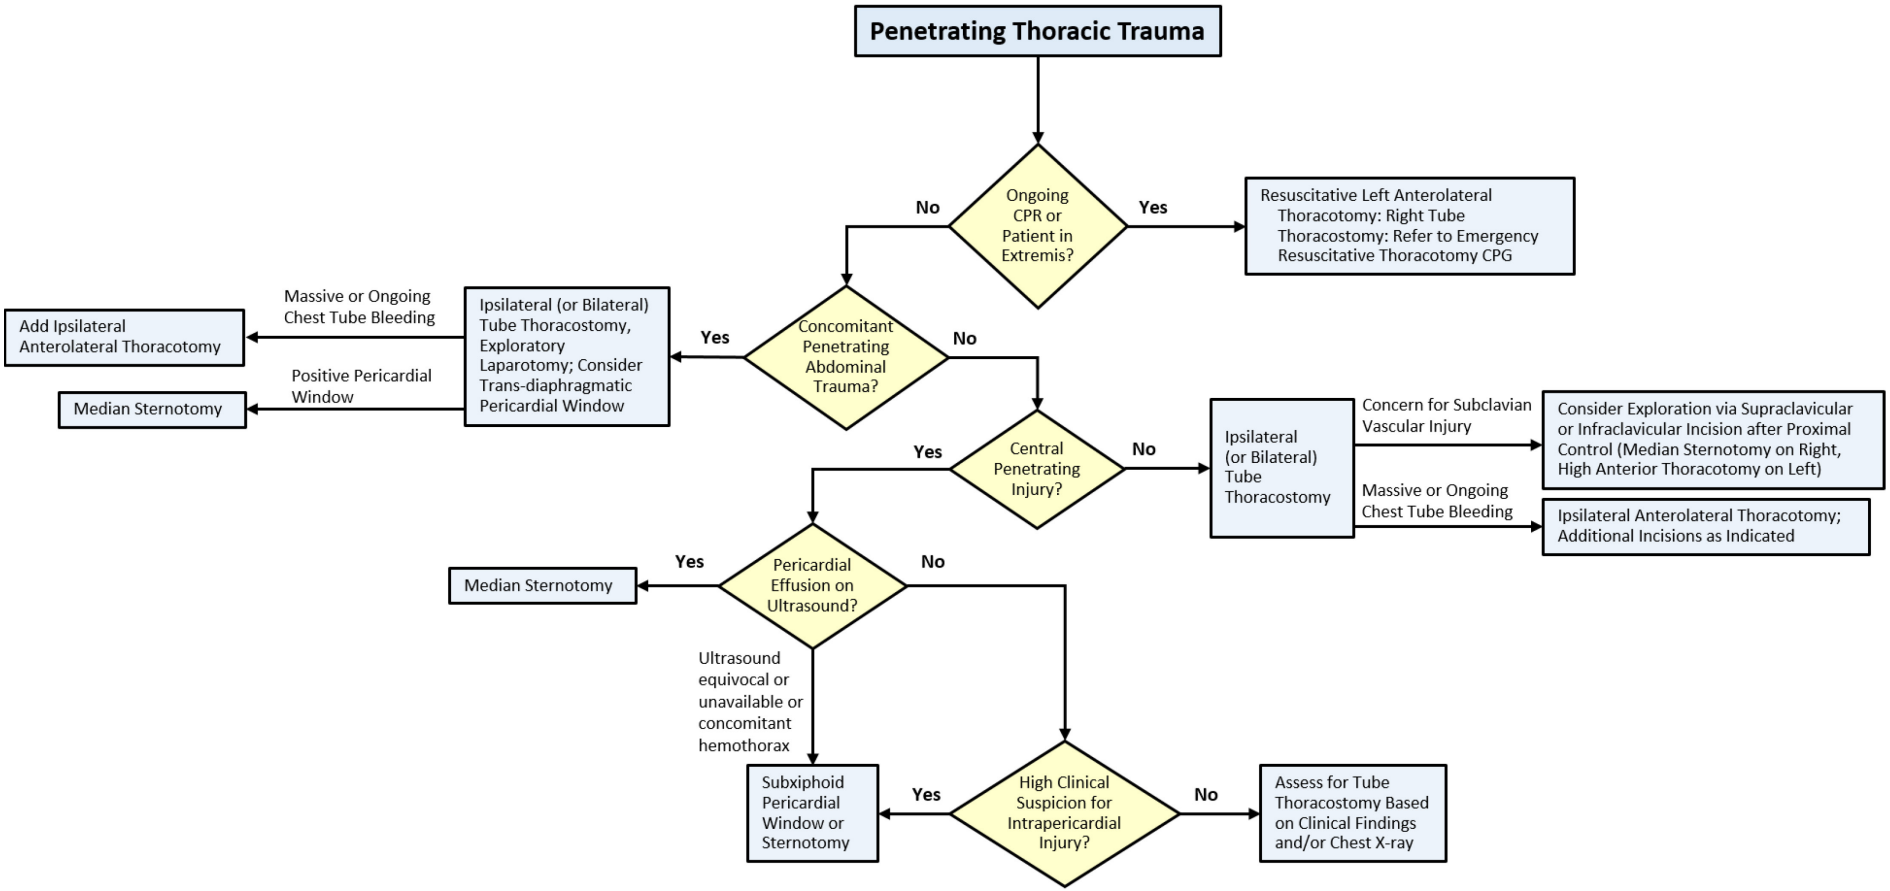
7. Posterolateral thoracotomy is rarely appropriate in the acute trauma setting. It is not appropriate in the damage control setting since it does not allow extension into frequently injured adjacent body cavities (abdomen, neck). It may be indicated for definitive repair of posterior mediastinal or lung injuries in a well-resuscitated patient after other injuries have been excluded or addressed.

8. In a patient with combined penetrating chest and abdominal trauma with hemodynamic instability, rapid insertion of bilateral chest tubes and midline laparotomy with pericardial window through the anterior diaphragm will allow for assessment of bleeding from all major body cavities. When needed, laparotomy can be extended to a sternotomy (for a positive pericardial window) or a separate anterolateral thoracotomy incision can be performed for ongoing pleural space hemorrhage. When the diaphragm is lacerated, an abdominal source of bleeding may present as bleeding into the chest cavity.

9. As described below, damage control philosophy and strategies apply to emergency thoracic surgery as well. Gauze packing and hemostatic adjuncts can help achieve temporary hemostasis of chest wall defects or injuries at the apex of the hemithorax.[13] Uncontrolled bleeding from the lung, pulmonary hilum or thoracic aorta can be packed as well.[14] Due to risk of iatrogenic tamponade, avoid packing of the pericardium.

10. Temporary chest closure can be considered after damage control procedures, or when there is concern for thoracic compartment syndrome due to massive resuscitation. Closure can be performed using a negative pressure vacuum closure or simply a large adhesive drape with a large-bore chest tube for drainage and suction.[14]

Figure 1. Algorithm for Surgical Management of Penetrating Thoracic Trauma



Penetrating Thoracic Trauma
Ongoing CPR or Patient in Extremis?
No
Yes
Resuscitative Left Anterolateral Thoracotomy: Right Tube Thoracostomy: Refer to Emergency Resuscitative Thoracotomy CPG
Concomitant Penetrating Abdominal Trauma?
Yes
No
Ipsilateral (or Bilateral) Tube Thoracostomy, Exploratory Laparotomy; Consider Trans-diaphragmatic Pericardial Window
Massive or Ongoing Chest Tube Bleeding
Add Ipsilateral Anterolateral Thoracotomy
Positive Pericardial Window
Median Sternotomy
Central Penetrating Injury?
Yes
No
Ipsilateral (or Bilateral) Tube Thoracostomy
Concern for Subclavian Vascular Injury
Consider Exploration via Supraclavicular or Infraclavicular Incision after Proximal Control (Median Sternotomy on Right, High Anterior Thoracotomy on Left)
Massive or Ongoing Chest Tube Bleeding
Ipsilateral Anterolateral Thoracotomy; Additional Incisions as Indicated
Pericardial Effusion on Ultrasound?
Yes
No
Median Sternotomy
Ultrasound equivocal or unavailable or concomitant hemothorax
Subxiphoid Pericardial Window or Sternotomy
High Clinical Suspicion for Intrapericardial Injury?
Yes
No
Assess for Tube Thoracostomy Based on Clinical Findings and/or Chest X-ray

DAMAGE CONTROL TECHNIQUES [14-18]

1. The goals of damage control surgery, hemorrhage and contamination control, are the same regardless of location of injury. While hemorrhage control remains paramount in damage control thoracic surgery, contamination from the alimentary tract is infrequently encountered from esophageal injuries. Damage control surgery is a staged approach to life-threatening injury. As applied to thoracic surgery in the combat setting, damage control surgery consists of:

    a. Rapid transport from point of injury to a higher level of care and recognition of need for DCS (Role 2,3).

    b. Rapid control of hemorrhage and contamination (Role 2,3).

    c. Resuscitation with restoration of physiology in intensive care setting (Role 2-4).

    d. Return to surgery for completion of operative repairs (Role 3, 4).

    e. Definitive chest closure (Role 3, 4).

2. Packing may be used as a complement to hemostatic efforts for hemorrhage from the chest wall, lung, and vascular structures that have been repaired. When packing, no pressure should be placed on the heart or major, low-pressure vasculature (i.e. superior vena cava, inferior vena cava, pulmonary artery).

3. There is a stepwise increase in mortality with more extensive resections when lung injuries are encountered. Tractotomy and limited wedge resection are associated with higher survival rates compared to lobectomy. Trauma pneumonectomy carries the worse prognosis with mortality rates ranging from 50-100%.

4. Pulmonary tractotomy is performed by opening a through-and-through injury tract with a gastrointestinal anastomosis (GIA) stapler (or between straight vascular clamps) followed by control of the bleeding edges and/or air leaks with additional staplers or a running suture repair using a non-cutting needle.

5. Damage control surgical techniques to temporarily control massive hilar hemorrhage include: the hilar twist maneuver, temporary hilar clamping, and intra-pericardial control of the ipsilateral main pulmonary artery with a Rommel tourniquet. These techniques should be prioritized in an effort to defer or avoid pneumonectomy.

6. A pneumonectomy may be warranted in unstable patients with massive parenchymal destruction, massive hilar hemorrhage, or extensive bronchial disruption beyond repair.

7. Acute right heart failure is the most common cause of death after trauma pneumonectomy. Rapid increases in pulmonary vascular resistance/pressure lead to increased right ventricular end diastolic pressure followed by shifting of the interventricular septum leftward, which ultimately leads to left ventricular dysfunction. Principles of treatment center on judicious volume resuscitation, inotropic support, and reduction in pulmonary vascular resistance and right ventricular afterload. Early ECMO team contact is indicated.

8. Medications

    - Dobutamine and milrinone provide positive inotropic effects and serve as moderate pulmonary vasodilators, lowering right ventricular afterload while improving function.
    - Inhaled nitric oxide (20-40 ppm through the ventilator) is a pure pulmonary vasodilator that also improves right ventricular function by lowering right ventricular afterload. These medications are typically only available in the Role 4 setting or higher.

9. Cardiac injury may be associated with intra-cardiac valve or septum injury. Maintain a high-index of suspicion for injury to more than one cardiac structure or hidden, intra-cardiac injuries.

10. Cardiac bleeding after penetrating injury can be controlled initially with a skin stapler or Foley balloon.

11. Open cardiac massage should be performed by compressing the heart between two flat hands from the apex towards the outflow tracts.

12. Temporary chest closure should be considered in the damage control setting or if there is concern for thoracic compartment syndrome (increased intrathoracic pressure causing decreased venous return and decreased cardiac output). It is performed in a manner similar to that of temporary abdominal closure. Thoracostomy tubes (or mediastinal drains) and sterile surgical towels or gauze are placed, followed by placement of an occlusive dressing. Negative pressure is then applied to the temporary closure. A wound vacuum system can also be utilized in this setting. When a vacuum sponge closure is used, direct contact between the sponge and lung tissue should be avoided.

13. Timing for return for definite chest closure is determined by adequacy of resuscitation and normalization of physiologic parameters, as evidenced by reversal of triad of hypothermia, acidosis, and coagulopathy.

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

All patients with chest injury of AIS code 2 or greater.

INTENT (EXPECTED OUTCOMES)

1. All patients in the population of interest with diagnosis of hemothorax or pneumothorax receive a tube thoracostomy prior to transport from the first surgical capability.

2. Patients in the population of interest who do not have a diagnosis of hemothorax or pneumothorax do not receive a tube thoracostomy.

3. In patients who receive needle decompression of the chest, the specific reason that tension pneumothorax was suspected is documented.

4. Patients with massive hemothorax > 1,500 ml undergo thoracotomy at the first surgical capability.

5. E-FAST results are documented in all patients with significant chest injury (AIS code 2 or greater).

PERFORMANCE/ADHERENCE METRICS

1. Number and percentage of patients in the population of interest with diagnosis of hemothorax or pneumothorax who had a tube thoracostomy placed prior to transport from the first surgical capability.

2. Number and percentage of patients in the population of interest who do not have hemothorax or pneumothorax who had a tube thoracostomy placed.

3. Number and percentage of patients who receive needle decompression of the chest who have the specific reason for suspected tension pneumothorax documented.

4. Number and percentage of patients who undergo thoracotomy or sternotomy at the first surgical capability, who have the indication for the procedure clearly documented.

5. Number and percentage of patients with significant chest injury (AIS code 2 or greater) who have E-FAST results documented.

DATA SOURCES

- Patient Record
- Department of Defense Trauma Registry (DoDTR)

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Chief and the JTS PI Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local level with this CPG.

APPENDIX A: SPECIFIC THORACIC PROCEDURES [19,20]

TUBE THORACOSTOMY

1. Antibiotic prophylaxis (with gram positive coverage) should be given prior to tube thoracostomy to reduce infectious complications, provided this will not lead to a clinically significant delay in treatment. [21, 22]

2. There is no need to position the ipsilateral arm over the patient's head.

3. If time allows, prep the anterior and lateral chest on the affected side and administer antibiotics prior to incision.

4. Plan an incision at nipple level (male) or at the inframammary crease (female), centered over the anterior axillary line.

5. Infiltrate local anesthesia for a stable, awake patient.

6. After a generous transverse incision (2-4cm) into the sub-dermal fatty tissues, a curved clamp is used to bluntly dissect the muscle and soft tissue down to the level of the rib. A blunt clamp is then directed over the top of the rib into the pleural space. A rush of air or blood out of the chest will confirm a pneumothorax or hemothorax respectively.

7. The clamp should be spread within the chest wall, followed by digital palpation to confirm pleural space entry, and insertion of a chest tube in an apical and posterior direction.

8. For combat trauma injuries, a chest tube size of at least 24-french is appropriate. In the setting of known or suspected hemothorax, a tube size of at least 28-french is desirable to reduce the risk of tube occlusion from clotted blood.

9. After the tube is sutured securely to the skin, it should be attached to a closed drainage system. In the field setting, a one-way Heimlich valve may be used for temporary drainage.

SUBXIPHOID PERICARDIAL WINDOW

1. Only appropriate for a stable patient. Prep the patent widely for potential sternotomy and/or thoracotomy.

2. After a 4–6 cm vertical midline incision centered over the xiphoid process, dissect through the skin and fascia with knife or electrocautery.

3. The xiphoid process can then be grasped/lifted with a Kocher clamp or can be excised with a heavy scissor or with electrocautery to facilitate exposure.

4. Blunt dissection deep to the xiphoid, directed in a cephalad direction will expose fatty tissue over the anterior pericardium. If the diaphragm is encountered, the dissection should be redirected in a more cephalad direction.

5. After removing or dissecting this fatty tissue to expose the underlying whitish pericardium, the pericardium should be grasped with a forceps or clamp and sharply incised.

6. Any gross blood in the pericardial space indicates a positive pericardial window and mandates sternotomy.

7. Clear pericardial fluid indicates no injury. Occasionally, absence of pericardial fluid may indicate clot in the pericardium and further investigation, such as irrigation with warm saline, should be performed.

8. There is no need to close the pericardium after a negative pericardial window.

TRANS-DIAPHRAGMATIC PERICARDIAL WINDOW

1. If there is concern for intra-pericardial injury in a patient undergoing laparotomy for penetrating trauma, a trans-diaphragmatic pericardial window is rapid and highly effective in evaluating for such an injury.

2. The central tendinous portion of the diaphragm is grasped with clamps and incised vertically for 3-4cm to expose the underlying whitish fibrous pericardium. The pericardium is then grasped and sharply incised to assess the pericardial space for any gross blood. If there is none, the pericardium need not be re-approximated, although the diaphragm should be repaired with permanent suture.

MEDIAN STERNOTOMY

1. Indicated for suspected cardiac/great vessel injury based on ultrasound or positive pericardial window. In the setting of an obvious concomitant pleural space hemorrhage, anterolateral thoracotomy is preferable to sternotomy (with plans for conversion to a clamshell or trap door incision as needed to expose the heart or great vessels).

2. Does not provide for adequate exposure of left subclavian artery, distal aortic arch, or descending aorta, and provides for only limited exposure of the pleural spaces.

3. Begins with midline skin incision from sternal notch to just below xiphoid process, followed by sharp/blunt dissection both superiorly and inferiorly just deep to the sternum.

4. The sternum is divided in the midline with a sternal saw or Lebsche knife.

5. Bone wax can be used to decrease bleeding on the cut edges of the sternum, and cautery should be used to control bleeding from the sternal periosteal edges.

6. Both pleural spaces should be entered and opened widely where possible. This is facilitated by elevating the hemi-sternum, briefly holding ventilation, then opening the pleura overlying the lung with scissors or electrocautery. After the pleural space is entered, a suction device should be introduced to evacuate any blood.

7. After opening the pleural spaces, a standard chest retractor is placed. Mediastinal fat will be visible and should be divided in the midline down to the level of the fibrous pericardium. At the superior

limit of the incision, the innominate vein will be located within the mediastinal fat and care must be taken to avoid injury to this structure.

8. The pericardium is then grasped and opened sharply in the midline. A finger is then inserted into the pericardial space to allow opening the midline pericardium down to the level of the diaphragm and up to the level of the innominate vein using scissors or electrocautery. The pericardium should then be opened laterally in either direction along the diaphragm to facilitate exposure.

9. Heavy sutures should be placed in the pericardial edges on both sides then tied under tension to the skin edges or secured under tension to clamps overlying the chest wall. These sutures will minimize interference from the ventilating lungs and facilitate exposure of the heart and great vessels.

10. A sternotomy can be extended into a neck exploration incision if there is concern for carotid, jugular, or tracheal injury. For suspected proximal right subclavian vascular injury, sternotomy can be extended to a right supraclavicular incision. For suspected proximal left subclavian vascular injury, the incision can be extended into an anterolateral thoracotomy (or to a trap door incision, described below).

11. There is no indication to re-approximate the pericardium. For sternotomy closure, chest tubes are placed into the mediastinum (and into any open pleural space) and the sternum is re-approximated with a series of heavy interrupted wire sutures. Typically 3 wires are placed through each side of the manubrium, 1-2cm from the edge of the bone. For the sternal body, 3-4 additional wires are placed directly through the halves of the sternum or around the sternum through the costal interspaces. If wire is not available, large permanent suture (e.g., polyester suture, #2 or larger) is appropriate.

12. For a patient undergoing sternotomy in the setting of hemodynamic instability or ongoing massive resuscitation, temporary chest closure is advised in most cases. After placement of a laparotomy pad or wound vacuum sponge beneath the edges of both sides of the sternum to avoid laceration of the heart from movement, an occlusive adherent dressing is placed and chest tubes are placed to suction to evacuate any residual bleeding.

ANTEROLATERAL THORACOTOMY

1. Refer to JTS CPG on Emergency Resuscitative Thoracotomy.[8]

2. Useful for massive hemothorax; allows access to lung parenchyma, hilum, chest wall, and subclavian vessels.

3. For proximal left subclavian control, anterior thoracotomy in the 3rd interspace (above the 4th rib) will generally be adequate. See JTS Vascular Injury CPG.[12]

4. For general access to the pleural space, the 4th interspace is centered over the pulmonary hilum. Anterolateral thoracotomy at this level will provide access to most structures within the chest. The inframammary crease overlies the 5th rib medially in most patients, and therefore this crease provides a reasonable landmark for a 4th interspace anterolateral thoracotomy.

5. After incision of the skin and soft tissues parallel to the clavicle, from one fingerbreadth off of the sternum medially to the anterior or mid-axillary line laterally, divide the pectoralis major muscle in

the direction of its fibers, then bovie or cut the remaining fibrovascular tissues down to the top of the rib at the desired interspace.

6. Incise the intercostal muscle over the rib with electrocautery, then enter the pleural space using a blunt clamp, protect the lung, and divide the remaining muscle over the rib. Stop the intercostal incision about two finger-breadths lateral to the edge of the sternum to avoid the mammary vessels, but carry the intercostal incision as far laterally as safely possible to allow for maximal exposure.

7. Place a rib-spreader into the wound.

8. If additional exposure is needed, division of the medial costal cartilage will allow for additional rib spreading, or the incision can be extended to include a sternotomy and clavicular incision. (See description of trap door incision below.)

9. For thoracotomy closure, after the placement of chest tubes through separate stab incisions, "pericostal" sutures should be placed around the upper and lower ribs at the incision. Typically 3-5 sutures are needed, and any heavy suture (#1 or larger) may be used (although monofilament suture may have more of a tendency to dig into the intercostal muscle tissue when tied). Care must be taken to avoid the intercostal bundle with these sutures, by hugging the top of the upper rib but avoiding the bottom of the lower rib.

10. After chest tube and pericostal suture placement, the muscle is reapproximated with absorbable suture and the skin closed with staples.

CLAMSHELL INCISION (BILATERAL THORACOSTERNOTOMY)

1. Highly versatile incision, which provides adequate surgical access to virtually any structure in the thoracic cavity (with the exception of the esophagus and descending thoracic aorta).

2. Rarely appropriate as an initial incision (due to high level of incisional morbidity). Generally implemented after anterolateral thoracotomy if there is suspicion for bleeding into the contralateral pleural space, or heart or great vessel injury, or when there is inadequate exposure for an ipsilateral pleural space injury.

3. After anterolateral thoracotomy, divide the sternum transversely with a Lebsche knife, Gigli saw, or heavy shears. Both internal mammary vascular pedicles will need to be divided and controlled with ties or clips; bleeding from these may be unrecognized until adequate perfusion has been restored.

4. Create a contralateral thoracotomy (generally in the same intercostal space). Place bilateral rib spreading retractors. After initiating retraction, use scissors or cautery to release the sternum from the anterior pericardium to improve exposure.

SUPRACLAVICULAR INCISION

1. Most often indicated for suspected proximal or mid-subclavian vascular injury.

2. After an incision one fingerbreadth above and parallel to the clavicle from the midline to the distal clavicle, superficial fatty tissues, lymphatics and venous branches are divided and controlled to

expose the sternal and clavicular heads of the sternocleidomastoid muscle and the carotid sheath (located between the two muscle bellies).

3. After division of the sternocleidomastoid muscle heads just above their distal attachments, the proximal subclavian artery and its branches will be palpable and visible.

4. The anterior scalene muscle will be visible coursing anterior to the subclavian artery (posterior to the vein) and may need to be divided for adequate exposure. If this is the case, it is critical to free up and preserve the phrenic nerve, which runs directly along this muscle in a transverse direction.

5. The subclavian vein will be anterior and caudal to the artery.

6. For complex injuries, division of the clavicle (with a Gigli saw) or removal of part of the clavicle may facilitate additional exposure. Alternatively a supraclavicular incision can be combined with a separate infraclavicular exposure (for more distal subclavian access) or with a third interspace anterolateral thoracotomy (for control of the left subclavian artery at its origin).

INFRACLAVICULAR INCISION

1. If there is a known subclavian venous injury, an infraclavicular incision may provide for better exposure. This approach also provides better exposure of the more distal subclavian artery and its branches.

2. After an incision one fingerbreadth below and parallel to the clavicle from the mid-clavicular level to the lateral border of the pectoralis muscle, the pectoralis major muscle is opened transversely in the direction of its fibers.

3. The underlying clavipectoral fascia and pectoralis minor muscle are divided to expose the distal subclavian and axillary vessels. In this location, the artery will be posterior and cephalad to the vein, and the brachial plexus cords are closely associated with the artery.

TRAP DOOR INCISION

1. Combination of clavicular (or neck) incision, partial or complete median sternotomy and anterolateral thoracotomy (described above).

2. May be useful for combined penetrating cervical and mediastinal injuries or a severe injury to the proximal subclavian vessel/branches.

3. Rarely used as an initial incision due to high incisional morbidity (including risk of injuring the ipsilateral phrenic nerve, brachial plexus, thoracic duct, or other structures).

4. May be necessary for inadequate exposure after sternotomy and clavicular incisions (for right-sided injuries), or after left anterior thoracotomy and clavicular incisions (for left-sided injuries).

5. After supraclavicular incision, perform complete median sternotomy or partial median sternotomy to 4th intercostal space.

6. Incise the skin, soft tissues and muscle out to the anterior axillary line.

7. Divide the sternum laterally with sternal saw or a Lebsche knife, ligate the left internal mammary vessels, and continue the incision into the pleural space above the appropriate rib as an anterolateral thoracotomy.

THORACOABDOMINAL INCISION

1. Indicated for combined thoracic and abdominal injuries. May be particularly helpful for retrohepatic vena caval exposure.

2. May be created by continuing a resuscitative thoracotomy incision medially and inferiorly across the costal margin into the abdominal midline or by creating a separate midline abdominal incision after thoracotomy.

POSTEROLATERAL THORACOTOMY

1. Provides optimal exposure for esophagus, chest wall, descending thoracic aorta, and posterior hilum.

2. Rarely appropriate in the acute trauma setting, particularly in a multiply injured or acutely bleeding patient. This incision limits ability to treat concomitant injuries, limits anesthesia access for additional resuscitation lines, and limits ability to protect the spine. In addition, it generally requires ipsilateral lung isolation (using mainstem intubation, bronchial blocker, or double-lumen endotracheal tube), and potentially places the contralateral lung at risk for injury due to pooling of blood or secretions.

3. May be appropriate at Role 3 or higher level of care for evacuation of retained hemothorax or for addressing a complex lung injury or esophageal injury.

4. If beanbag is available, place on OR table; otherwise use large IV bags wrapped in towels placed in front of and behind the patient to secure him/her in a stable lateral position (in addition to strapping and taping the patient's hips and legs to the table).

5. Once the patient is in a secure lateral decubitus position, place a pillow between the legs, place the lower arm on an arm board straight at the elbow but flexed slightly at the shoulder, and place the higher arm in a flexed position at the elbow on a pillow or folded blankets.

6. After a wide prep and draping, mark mid-way between the medial border of the scapula and the vertebrae. Make a second mark one fingerbreadth below the inferior-most tip of the scapula. A posterolateral thoracotomy should connect these two marks in a gentle curve, then continue anteriorly parallel to the ribs.

7. After incising the skin and fatty subcutaneous tissue, divide the latissimus dorsi muscle transversely in the posterior aspect of the incision. The serratus anterior muscle, which runs anterior and deep to the latissimus, can be partially divided or mobilized and retracted anteriorly.

8. For most trauma situations, entering the chest right above the level of the tip of the scapula will provide an appropriate level for adequate exposure. After using electrocautery to divide the intercostal muscle along the top of the rib at this interspace, enter the pleural space with a blunt

clamp. Then pack the lung away with a moist laparotomy pad to allow extension of the intercostal incision widely along the top of the rib.

9. Encircling the lower rib at the posterior aspect of the incision with a right angle (taking care to avoid the intercostal bundle injury) will allow division of the rib with a rib shear to facilitate adequate retraction and exposure. However, this step is not mandatory. The creation of a "controlled fracture" by gradually opening a rib spreader will have the same desired effect of allowing adequate space to fit a hand comfortably into the pleural space.

10. Place a rib spreader.

11. For thoracotomy closure, after the placement of chest tubes through separate stab incisions, "pericostal" sutures should be placed around the upper and lower ribs at the incision. Typically 3-5 sutures are needed, and any heavy suture (#1 or larger) may be used (although monofilament suture may have more of a tendency to dig into the intercostal muscle tissue when tied). Care must be taken to avoid the intercostal bundle with these sutures, by hugging the top of the upper rib but avoiding the bottom of the lower rib.

12. After chest tube and pericostal suture placement, the muscle is reapproximated with absorbable suture and the skin closed with staples.

APPENDIX B: SPECIFIC THORACIC INJURY MANAGEMENT [19,20]

OPEN PNEUMOTHORAX

1. Treat by placing a chest tube through a separate incision and sealing the hole with an occlusive dressing. Complex chest wall defects may eventually require closure with mesh or muscle flap coverage at higher roles of care.

2. For patients with difficulty breathing, hypoxia or with large sucking chest wounds, maintain a low threshold to intubate prior to transport as positive pressure ventilation will overcome the effect of the sucking chest wound.

FLAIL CHEST

1. Generally associated with significant underlying lung contusion, which must be managed aggressively with supplemental oxygen and a low threshold for intubation and mechanical ventilation prior to air transport (or protracted ground evacuation).

2. In an awake patient with flail chest, pain control is critical to optimize pulmonary mechanics, although the use of intravenous narcotics must be balanced with the risk of respiratory depression.

3. Tube thoracostomy is appropriate prior to medical evacuation for any patient with flail chest, regardless of whether a pneumothorax or hemothorax is clinically evident.

4. There is a role for surgical stabilization of rib fractures (SSRF) in patients with flail chest or select patients with severely displaced rib fractures. SSRF should not be performed in a contaminated field, requires specialized equipment, and should only be done by surgeons familiar with the technique. For casualties undergoing further evacuation, SSRF should usually await Role 4 care. When performed, the original chest tube should be removed, the site cleaned and if possible excluded from the operative field and a new chest tube placed to reduce the risk of post-operative wound infection and osteomyelitis.

THORACIC VASCULAR INJURIES

1. The initial management of a thoracic vascular injury should be manual occlusion with a finger (for an artery) or a sponge stick (for a large vein). Temporary control can allow for additional resuscitation and exposure prior to attempted repair. For an aortic injury, a side-biting clamp may be placed (after aortic mobilization) for temporary control.

2. Repair of vessels should follow the principles detailed in the JTS CPG on Vascular Injuries, with shunting or repair by autogenous or synthetic grafts as indicated.

3. Incising the inferior pulmonary ligament mobilizes the lung to provide better exposure.

CARDIAC INJURIES

1. Isolated cardiac injuries are exposed by opening the pericardium and placing pericardial stay sutures.

2. Temporary control may be achieved with digital pressure, the use of a Foley catheter, or with skin staples.

3. For definitive repair, use pledgeted horizontal mattress sutures (2-0 or 3-0 polypropylene) on a large, tapered needle (MH or SH). Autologous pericardium can be used if commercial pledgets are not available. Sutures must be tied only to the point of hemostasis to avoid tearing potentially friable cardiac muscle. Take care to place sutures to avoid ligating coronary vessels.

4. Atrial injuries may be controlled with a side-biting clamp, followed by running closure with 2-0 or 3-0 polypropylene suture.

5. Temporary inflow occlusion (occluding the superior and inferior venae for brief intervals) may prove helpful in repair.

6. If distal coronary artery injuries are identified, they should be ligated to control the bleeding.

PARENCHYMAL LUNG INJURIES

1. Posterolateral thoracotomy is preferred for isolated lung injuries, but is only appropriate in a stable patient with adequate resuscitation and no other uncontrolled injuries. Anterolateral thoracotomy is more appropriate in the urgent or damage control setting.

2. Simple pulmonary parenchymal tears/bleeding may be repaired with absorbable suture on a tapered needle, or may be repaired with stapling of the lung parenchyma (with a GIA or TA middle-thickness staple load).

3. For deeper through-and-through injuries, a tractotomy may be performed by opening the injury tract with a GIA stapler or between straight vascular clamps, followed by running suture repair to control bleeding and air leaks from the exposed lung parenchyma.

4. For more severe/destructive lung injuries, non-anatomic partial lung resection with serial GIA stapler fires may be needed.

5. Hilar injuries or large parenchymal injuries with uncontrolled bleeding or massive air leak may require manual control of the hilum followed by hilar clamping for temporary control. Good communication with the anesthesia provider is essential to manage the resultant sudden decrease in lung volume and right heart strain. If repair is still not possible, pneumonectomy should be considered as a last resort due to the low survival associated with pneumonectomy in a trauma setting.

TRACHEOBRONCHIAL INJURIES

1. Airway control is the most important priority, and should be combined with tube thoracostomy(s). If after endotracheal intubation in a patient with a suspected airway injury, ventilation appears adequate and there is no other surgical indication, further intervention should be deferred to a higher role of care.

2. If there is difficulty with ventilation of the patient after tube thoracostomy due to a large air leak, the chest tube should be placed to water seal instead of suction.

3. When intervention is needed, median sternotomy (with cervical extension) provides exposure for the proximal and mid-trachea. Alternatively, cervical tracheal injuries can be approached from a collar incision. The distal trachea, carina, and proximal mainstem bronchi can only be visualized well via right posterolateral thoracotomy (with appropriate lung isolation). Injuries to the distal left mainstem bronchus or more distal left-sided bronchial tree generally require left thoracotomy for repair.

4. Tracheobronchial repair should employ absorbable suture (e.g., polydiaxanone or polyglactin), buttressed with pleural tissue or with intercostal or strap muscle wherever possible.

ESOPHAGEAL INJURIES

1. Most often will be identified during the course of exploration for other penetrating mediastinal injuries.

2. Although the resources for definitive repair may not be available in a deployed setting, the key principles in treatment are 1) adequate fluid resuscitation, 2) broad spectrum antibiotics, 3) debridement of any clearly non-viable tissue, 4) control of ongoing contamination, and 5) wide drainage.

3. For patients undergoing damage control procedures, chest tube drainage and a nasogastric tube placed above the level of injury are temporizing measures.

4. The preferred approach for intrathoracic esophageal injuries in a stable patient is posterolateral thoracotomy: right for the upper and mid-esophagus and left for the lower esophagus. Incising the inferior pulmonary ligament mobilizes the lung to provide better exposure.

5. Locate the injury by mobilizing the esophagus (aided by placement of a nasogastric or orogastric tube). Where possible, primary repair is preferred. After mobilizing the esophageal muscle above and below the mucosal injury to ensure complete visualization of the defect, the injury is repaired with a single layer or two layers of 3-0 absorbable sutures.

6. Buttress with muscle (intercostal or strap muscles, pericardium, diaphragm, etc.) should be used. Do not wrap the repair circumferentially. Drains should be placed near the repair.

7. If primary repair is not possible, wide drainage with proximal esophageal diversion should be considered. Resection should only be utilized in the setting of extensive tissue devitalization.

DIAPHRAGM INJURIES

1. Most often encountered at the time of abdominal exploration, all injuries of the diaphragm should be closed. If identified at the time of thoracotomy, one must evaluate for associated intra-abdominal injury. In the damage control setting, repair of diaphragm lacerations can be deferred until re-exploration.

2. The majority of injuries can be repaired with nonabsorbable running or interrupted sutures, 2-0 or larger. Mesh repair may be necessary but should be used with caution in the face of contamination.

3. Central tendon injuries of the pericardial diaphragm are rare, but when they occur they can cause tamponade physiology due to either cardiac herniation into the abdomen or herniation of the small or large intestine into the pericardium. Prior to closing central tendon tears, copiously irrigate the pericardial space with warm saline to wash out blood clots or enteric contents and carefully inspect the heart and pleural pericardium to ensure there are no other injuries or tears.[23]

CHEST WALL BLEEDING

1. Unlike bleeding from the low-pressure vascular system of the lung parenchyma, bleeding from intercostal arteries reflects systemic pressure and often will not resolve with tube thoracostomy alone.

2. Chest wall bleeding will typically be encountered after an anterolateral thoracotomy for massive or persistent chest tube bleeding. After assessing for non-chest wall bleeding sources, chest wall bleeding can almost always be temporized with manual pressure and packing. Temporary cessation of ventilation may allow for more accurate assessment and control of a chest wall bleeding site.

3. One must be cognizant of the subclavian vessels, which are closely associated with the anteroapical chest wall. If significant chest wall bleeding appears to be arising from this location, additional supra- or infraclavicular incisional exposure may be needed.

4. Once a direct site of chest wall bleeding is identified, it can be controlled with clips, suture, or cautery. Placing figure-of-eight pericostal sutures using a large, blunt needle (CT or MH) around the involved rib (proximal and distal to the bleeding site) may be effective.

5. Adequate visualization may require enlarging an incision, or making a separate counter-incision to improve the angle of approach.

6. In an unstable patient, chest wall bleeding can be temporized with packing using gauze or hemostatic adjuncts.

CONCOMITANT INJURIES

1. As described above, the management of patients with suspected combined thoracic and abdominal penetrating injury depends on initial stability.

2. In the face of hemodynamic collapse or loss of vital signs, emergency resuscitative thoracotomy is indicated for temporary control of thoracic bleeding, assessment for intra-pericardial bleeding, control of the descending thoracic aorta, and open cardiac massage.

3. In unstable patients with combined thoracic and abdominal injuries, or when CT scan is not available, midline laparotomy with tube thoracostomy (unilateral or bilateral, depending on injury pattern) and trans-diaphragmatic pericardial window is a safe approach.

4. For patients with combined injuries of the neck and chest, a cervical incision can easily be extended into a median sternotomy (for cardiac or great vessel injury or for proximal control of the right subclavian or either carotid artery), or into right or left supra- or infraclavicular incisions (for subclavian vascular injuries). In addition, a separate anterior or anterolateral thoracotomy may be indicated based on tube thoracostomy output or the need for proximal control of the left subclavian artery.

TRANS-MEDIASTINAL WOUNDS

1. Penetrating wounds which traverse the mediastinum via one or both pleural spaces represent a highly complex injury pattern, and every intra-thoracic structure is at risk. Intra-cardiac injuries (valve or septal injury) should also be suspected with this pattern of injury.

2. At the Role 2 level, care for suspected trans-mediastinal injury (after ensuring adequate airway and intravenous/intra-osseous access) should consist of bilateral tube thoracostomy and assessment for intrapericardial bleeding. Following the algorithms outlined above, surgical intervention may be appropriate. For unstable patients with suspected trans-mediastinal penetrating injury, a left anterior thoracotomy with right chest tube should be performed, with conversion to clamshell incision when needed to address intrapericardial or right chest bleeding.

3. At the Role 3 level with a hemodynamically stable patient, CT imaging should be performed to better estimate the missile trajectory(s), allowing a determination of structures at high risk for injury (keeping in mind that high-velocity weapons can inflict significant destruction outside the direct missile path). Using intravenous contrast with the CT allows assessment for vascular injuries without the need for invasive diagnostic angiography. Where available, esophagoscopy and bronchoscopy may be indicated if there is clinical or radiographic evidence of esophageal or tracheobronchial injury, respectively. Echocardiography can be utilized to assess for cardiac valvular injuries or septal defects. Definitive repair of these injuries can usually be delayed and should await Role 4 where the appropriate expertise and support is available.

RETAINED HEMOTHORAX

1. Retained hemothorax is defined as undrained blood after 72 hours of tube thoracostomy drainage. Except under extenuating circumstances (such as protracted delay for medical evacuation), the treatment of retained hemothorax should be deferred to Role 3 or higher where CT imaging is available.

2. If a retained hemothorax is suspected by a chest X-ray, CT imaging should be obtained. If the volume of undrained blood is estimated at greater than 300cc and if it is felt to be clinically significant, then additional drainage intervention should be considered.[24]

3. Additional drainage procedures may consist of an additional tube thoracostomy (low yield after 24 hours), video assisted thoracoscopic surgery (VATS) drainage, image-guided drainage catheters or instillation of intrapleural thrombolytics. None of these approaches has demonstrated clear superiority.[25] Thoracotomy may be required if less invasive interventions fail.

4. The intra-pleural administration of thrombolytics is an established but unproven adjunct to chest tube drainage for retained traumatic hemothorax. In the absence of active bleeding or other typical contraindications to thrombolytic therapy and in the absence of an ongoing air leak (which would contraindicate a period of clamping the chest tube), 50mg of altepase (tPA) in 100ml of normal saline may be administered into the pleural space via chest tube utilizing sterile technique. The chest tube should be clamped for several hours, then placed back on suction. This treatment can be repeated daily for up to three days. tPA will generally be available in a 1mg/ml concentration, such that the 50mg/50ml dose of tPA should be combined 1:1 with 50ml of sterile saline.

APPENDIX C: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Whole Blood Transfusion (CPG ID: 21)

This CPG provides the rationale and guidelines for WB transfusion, including but not limited to product definitions, indications, collection, storage, testing, transfusion, and documentation.

DEFINITIONS

Whole blood (WB) collected in the anticoagulants CPD or CPDA-1 is an FDA-approved product when it is appropriately collected, stored and tested for transfusion transmitted disease (TTD) by a licensed blood donor center. It can be stored for 21 days at 1-6°C in CPD or 35 days at 1-6°C in CPDA-1 and is designated stored whole blood (SWB) in this CPG. SWB retains in vitro hemostatic parameters to an acceptable level during approved storage duration.[1] However, after the first 2 weeks of storage, the hemostatic function of WB may vary and supplementation with fresher whole blood units or blood components, especially platelets, may be necessary.

Fresh whole blood (FWB) refers to WB collected on an emergency basis from a "walking blood bank" (WBB). FWB can either be stored at room temperature and used within 24 hours of collection (and then destroyed if not used) or it can be refrigerated within 8 hours of collection, after which point it becomes WBB-SWB. FWB is considered to have full hemostatic function. FWB is collected from pre-screened donors when possible, but does not undergo TTD testing prior to transfusion; this fact makes it not approvable by the FDA. Because FWB presents a higher risk of disease transmission, it is reserved for situations in which tested blood products are unavailable or ineffective (further discussion below).

The most important safety consideration in transfusing WB is that donor red blood cells (RBCs) be compatible with the recipient to avoid acute hemolytic transfusion reactions (a.k.a., major mismatch). WB from group O donors contains RBCs that are compatible with all recipients, but the plasma in group O WB may contain anti-A and anti-B antibodies that could cause hemolysis in a non-group O recipient (a.k.a., minor mismatch). There are two approaches to mitigating this risk: 1) transfuse only group-specific WB (i.e. A to A, B to B, AB to AB and O to O), or 2) anti-A and anti-B antibody titers can be measured in group O WB and only units containing a low titer of antibody (e.g., <1:256 saline dilution, immediate spin method) are designated "low titer O WB" (LTOWB) and these are used as "universal WB." LTOWB has been used extensively to resuscitate combat casualties and was a standard of care in WWII, and the conflicts in Korea and Vietnam.[2] Note that LTOWB may be either SWB or may be collected from pre-screened O donors in a WBB protocol and thus be considered FWB (e.g., the Ranger O Low titer or ROLO protocol).[3] In practice, the only SWB supplied by the Armed Services Blood Program (ASBP) to OCONUS locations will be LTOWB due to the relatively higher risk of donor-recipient blood group mismatch and resulting hemolysis during group-specific WB transfusion, compared to the much lower risk of hemolysis with LTOWB.[2] Collecting LTOWB from WBB pre-screened donors is also preferred to group-specific transfusion. In short, most WB transfused during future contingency operations will be LTOWB, and most of this is likely to be SWB. Use of LTOWB is recognized under AABB Standard 5.15.1 (31st Edition, AABB Standards, in effect beginning 01 April 2018).[4]

It should be noted that anti-A and anti-B titers may vary in group O donors. Ideally, WBB donors should be re-titered every 90 days in conjunction with TTD testing. However; since availability of titer testing in the deployed setting is very limited, every effort should be made to ensure that donors are titered at least annually if not prior to each deployment. ASBP collects WB from male and never-pregnant female donors, or from female donors testing negative for anti-HLA antibodies (this mitigates risk of transfusion-associated acute lung injury, TRALI). WB is primarily collected from Rh positive donors and there is a limited supply of Rh negative blood products in the deployed environment. Every effort should be made to provide Rh negative whole blood or red cells to females of child-bearing potential (age<50 years) who are Rh negative or of unknown blood type. However; should transfusions of Rh positive blood products occur in these patients, these must be thoroughly documented in the patient's medical record due to the risk of allo-immunization to Rh and potential for hemolytic disease of the fetus/newborn (HDFN) in future pregnancies.

All WB products (SWB, FWB, and LTOWB) are indicated for the resuscitation of massive blood loss. WB, and in particular LTOWB, is the preferred resuscitation product for the pre-hospital treatment of patients in hemorrhagic shock.[5,6] This CPG will distinguish between stored whole blood (SWB) and fresh whole blood (FWB), and discuss uses and limitations of both products.

BACKGROUND

The first documented animal-to-animal (dog) blood transfusion was performed at Oxford in 1665 by Richard Lower, followed by the first animal-to-human blood transfusion in 1667 by Jean Denis. The first human-to-human blood transfusion was performed by James Blundell in 1818. In the year 1900, the ABO blood grouping system was classified by Landsteiner and, based on this, the first pre-transfusion cross-match was done by Ottenberg in 1907. The system of Rh typing was invented by Landsteiner and Wiener in the year 1940.[7] In military settings, whole blood has been used extensively to resuscitate casualties in military conflicts since 1917, during World War I.[8] Whole blood is the starting point for blood donation and continues to be used extensively worldwide where component production is not available.

Blood safety and sustainability are global issues. Component development supports the sustainability of blood services where demand can outstrip supply. Component use also permits optimal storage conditions for each element of the blood, minimizes hemolytic reactions and supports precision treatment. Examples include the use of red blood cells (RBCs) for anemia, fresh frozen plasma (FFP) to replace lost or consumed clotting factors, platelets (PLTs) for platelet abnormalities and thrombocytopenia, and cryoprecipitate (Cryo) for hyperfibrinogenemia. Whole blood contains all of these elements in a smaller volume of anticoagulant and thus provides a more concentrated product for treating bleeding patients who need all elements of blood replaced. The widespread use of component therapy is driven by blood product availability. For the reasons outlined above, blood banks have preferred to stock components over WB.

The clinical data comparing WB to components have recently been reviewed.[6] Currently available clinical data indicate that use of WB to treat hemorrhage results in outcomes that are at least as favorable as those that can be expected with component therapy that includes RBCs, plasma and platelets.

Severely injured combat casualties requiring transfusion have a significant mortality rate (16%) and have the greatest potential to benefit from early and appropriate transfusion strategies. A large retrospective cohort study of casualties requiring transfusions during Operations Iraqi Freedom (OIF) and Enduring Freedom (OEF) suggests a significant survival benefit for transfused casualties when RBCs, fresh frozen plasma, and platelets are transfused at a 1:1:1 ratio.[9] A recent randomized trial in civilian trauma patients demonstrated that a 1:1:1 transfusion ratio resulted in improved early hemostasis, though no statistically significant improvement in survival.[10] Two retrospective analyses in combat casualties comparing FWB to component therapy (which included platelets) have also been published. One study showed a potential survival benefit to the use of FWB during resuscitation of severe combat injuries, and the other showed FWB to be equivalent to component therapy.[11,12] These studies underscore the importance of providing all elements of whole blood (RBCs, plasma and platelets) to severely bleeding patients and suggest that use of either WB or components in a 1:1:1 ratio for resuscitation of bleeding patients is acceptable; product choices can be guided by practical considerations.

ADVANTAGES OF WHOLE BLOOD OVER COMPONENTS

SWB and FWB provide FFP:RBC:PLTs in a physiologic ratio and return to the bleeding patient what has been lost. It should be noted that the 1:1:1 ratio of blood components (platelets: plasma:RBC) recommended for damage control resuscitation does not faithfully reconstitute WB. The 1:1:1 ratio yields a dilute blood mixture with a hematocrit of 29%,[13] a platelet count of approximately 90,000/µL, and coagulation factors diluted to approximately 62% of WB concentrations due to the presence of anticoagulants and red cell additive solution. In addition, WB delivers all needed elements of blood in only one product, which only requires refrigeration for storage. In contrast, component therapy requires multiple products and storage modalities (refrigeration, freezing and generally room temperature storage with agitation for platelets – though platelets can also be refrigerated), greatly increasing workload and complexity for clinical teams.

SWB collected in licensed blood centers offers the same level of TTD safety as component therapy collected in licensed centers. It should be noted that due to the extremely short shelf life of standard room temperature stored platelets (5 days), all platelet products transfused in the deployed setting are collected in theater and do not undergo TTD testing prior to transfusion. Therefore, SWB collected in licensed centers and fully tested presents a lower TTD risk than component therapy using in-theater collected platelets or FWB.

For U.S. casualties presenting in hemorrhagic shock, a transfusion strategy that included FWB with RBCs and plasma was associated with an improved survival compared to the use of stored components only (FFP, RBCs, and PLTs).[11] Compared to SWB or component therapy, FWB is more readily available in austere conditions and requires only the presence of donors and simple collection equipment, though safe collection and transfusion of FWB requires appropriate pre-deployment training [14,15] and careful donor evaluation. FWB has no loss of the labile clotting factors or platelet activity that is often associated with storage, has close to physiological hematocrit and has no red blood cell "storage lesion." Storage lesion describes the degradation of the RBC involving loss of membrane plasticity,[11,12] diphosphoglycerate, adenosine triphosphate, nitric oxide, and other factors leading to potentially reduced delivery of oxygen to tissues and contribution to a variety of pathophysiologic processes.[16] It should be noted that recent randomized trials assessing the effects of red blood cell storage age have not confirmed a clinically detectable deleterious effect of the red cell storage lesion in the populations evaluated. The effect of red cell storage age, whether in component therapy or SWB has not been rigorously evaluated in certain vulnerable populations, such as trauma patients.[17]

Overall, both SWB and FWB offer at least comparable performance and safety compared with components, as well as compelling logistical advantages that are particularly important in pre-hospital resuscitation and indeed, in most deployment settings.

CONSIDERATIONS IN CHOOSING SWB OR FWB

There are risks associated with the use of FWB, including but not limited to increased risk of transfusion-transmitted infections (e.g., HIV, hepatitis B/C, syphilis), and an increased risk of clerical errors leading to major mismatch when ABO-identical WB is provided, due to the potentially chaotic conditions during which FWB is requested. Additionally, field conditions are inherently unsanitary and are presumed to increase the risk of bacterial contamination of the blood. Recent history with approximately 10,000 FWB transfusions to U.S. personnel during OIF/OEF have resulted in one Hepatitis C (HCV), one Human T-Lymphocyte Virus (HTLV) seroconversion, and one fatal case of transfusion-associated graft-versus host disease that was potentially due to a FWB transfusion.[4] FWB is not FDA-approved and is not intended or indicated for routine use. It is NOT appropriate, as a matter of convenience, to use FWB as an alternative to more stringently controlled blood products for patients who do not have severe, immediately life-threatening injuries. FWB is to be used only when other blood products cannot be delivered at an acceptable rate to sustain the resuscitation of an actively bleeding patient, when specific stored products are not available (e.g., SWB, RBCs, FFP, PLTs, Cryo), or when stored components are not adequately resuscitating a patient with an immediately life-threatening injury. FWB should not routinely be collected from pre-screened donors as a way to maintain a routine inventory of WBB-SWB products. In other words, the use of WBB for collection of FWB is for emergency use only. It should be noted that studies of FWB donors have not documented significant decrements in military-relevant task performance following donation. Thus, concerns that FWB collections will adversely affect mission outcomes have not been substantiated and should not preclude WBB activation when conditions for FWB use are met.[18]

In patients receiving LTOWB (SWB or FWB), every effort should be made to obtain a pre-transfusion blood sample in order to establish the original blood group. If blood samples are obtained after transfusion with LTOWB, it may be impossible to definitively establish a patient's blood group with the equipment available in the deployed setting. As a result, patients of unknown blood group receiving LTOWB will continue to receive LTOWB or group O RBC units for their acute transfusion requirements for up to a month following admission. This can deplete inventories of LTOWB and group O RBCs.

WHOLE BLOOD RECOMMENDATIONS

- SWB, which will in practice be LTOWB, is the preferred product for pre-hospital resuscitation.
- In a facility capable of providing surgical care (Role 2 or higher), SWB (in practice, LTOWB) or component therapy (including RBCs, plasma and platelets) can used for damage control resuscitation. SWB simplifies transfusion and may facilitate more rapid resuscitation of casualties, and may enhance a facility's capacity to manage MASCAL challenges.
- The use of FWB should be reserved for casualties with clinically significant shock or coagulopathy (e.g. bleeding with associated metabolic acidosis, thrombocytopenia or INR>1.5) and when SWB or optimal component therapy (e.g., apheresis platelets and FFP) are unavailable, or when stored component therapy is not adequately resuscitating a patient with immediately life-threatening injuries.

GUIDELINES FOR WALKING BLOOD BANK PROGRAM FOR FWB

The decision to use FWB is a medical decision that must be made by a physician who has full knowledge of both the clinical situation and the availability of compatible blood products. A Walking Blood Bank (WBB) Program should be established based on a risk assessment and the potential for casualties. The calculation of risk should include a medical intelligence assessment which includes infection prevalence and the need for preventative force protection measures. In practice, all forward-deployed MTFs should establish a WBB. Coordination with the Area Joint Blood Program Officer (AJBPO) is required to establish a WBB Program. (Appendix B: Blood Donor Pre-screening Standard Operating Procedure [SOP]). FWB should be collected for transfusion as outlined in Appendix C: Emergency Whole Blood Drive SOP. In general, the use of FWB should be limited to casualties who are anticipated to require a transfusion when the physician determines that SWB or optimal component therapy is unavailable or in limited supply, or in patients that are not responding to SWB or component therapy. The decision to initiate a FWB drive should be made in consultation with the appropriate MTF medical authority (e.g., Deputy Commander for Clinical Services (DCCS), Trauma Director, Trauma Surgeon) and Laboratory/Blood Bank OIC. At Role 2 facilities, the lead surgeons and/or facility OIC should be consulted on the decision to initiate the drive.

Pre-screened donors registered into the WBB Program are preferably composed of active duty, active reserve, active National Guard, and other DoD beneficiaries. The preferred donors for FWB are fully pre-screened, low titer O donors. Next, consider fully pre-screened donors of other blood groups for group-specific transfusions (e.g., A to A). Donors who have not been pre-screened for TTDs should be considered only when no other donors are available. Note that in chaotic circumstances such as tactical care under fire or mass casualty (MASCAL) scenarios, or if blood grouping equipment is not available in adequate quantities, use of group O FWB of unknown anti-A and anti-B titer may be safer than attempting to match blood groups between donors and recipients, since the risk of hemolysis from major mismatch is greater than the risk of transfusing a very high titer group O unit (very high titers units being relatively uncommon) to a non-group O recipient. Indeed, this strategy was successfully employed by a Forward Surgical Team in Afghanistan.[19]

Donors should be screened to international mandated and national standards. Coalition Forces will not be utilized routinely as donors, due to national variances in screening for blood borne diseases and differences in disease prevalence. Blood may be collected from pre-screened coalition partner forces if the screening program has been reviewed by the JBPO and deemed acceptable by the COCOM Surgeon and the ASBP Director. Planned coalition activity should address the interoperability of donor panels. Non-Coalition Force foreign nationals should be used as a last resort.

The decision to use FWB that has not been completely screened for infectious agents is a medical decision that must be made after thorough consideration of risks and benefits. Decision-making should be adequately documented in the casualty record.

The blood type on identification tags is occasionally incorrect (last correlated data equated to about 4% inaccurate) [20-22] and must not be relied upon routinely to determine blood type for either donors or recipients. Identification tags for ABO/Rh verification should be utilized as a last resort only.

Use of non-standard blood donation material and equipment may lead to coagulation during the collection process potentially causing an adverse transfusion reaction; therefore, only authorized equipment will be utilized (Appendix C enclosure: WBB Supply List [with NSNs]).

Prior to issuing FWB for transfusion, the ABO and Rh type should be verified and approved rapid infection disease tests (e.g., HIV, HCV, and HBV) should be performed as outlined in Appendix C: Emergency Whole Blood Drive SOP to the greatest extent possible.

Theater Medical Data Stores (TMDS), Blood Portal, shall be utilized to record FWB donations and infectious disease testing results.

Frequency of FWB donation must be tracked. In general, WB units should not be collected from donors more frequently than every 8 weeks (56 days). This interval between donations is important to allow the donor to recover RBC mass and iron stores and should not be shortened except under the most extreme circumstances. Donors who give blood frequently may develop iron deficiency even in the absence of anemia. Iron deficiency can cause fatigue, difficulty concentrating, pica, restless leg syndrome (RLS), and eventually anemia if untreated. Iron deficiency can be diagnosed by measuring serum ferritin levels (deficiency defined as ferritin <30 mcg/L in males and <20 mcg/L in females). In deployed settings, it may be impossible to measure ferritin levels but donors at particular risk of iron deficiency include: young donors (to early 20's), premenopausal females, frequent donors (males ≥ 3x/year, females ≥ 2x/year), and donors near hemoglobin cutoff for donation (males 13.0 g/dL, females 12.5 g/dL). Consideration should be given to screening ferritin prior to deployment in high risk donors, particularly low titer O donors who may be called upon to donate more frequently. Consideration should be given to empiric iron supplementation in high risk donors or donors with symptoms of iron deficiency (available as ferrous sulfate 325mg (65mg elemental iron), ferrous gluconate 325 mg (38mg elemental iron), or multivitamins with iron (18-19 mg elemental iron); one tablet per day for 60-120 days may be adequate to replete iron stores).[23,24] Patients with documented iron deficiency (low ferritin levels as above) should be offered iron supplementation and monitored for response.

WBB PLANNING

Since the need for FWB cannot be predicted, a robust contingency operational plan should be developed by the MTF staff to include the Laboratory/Blood Bank and surgical and anesthesia providers in coordination with the Area Joint Blood Program Officer. The plan should be reviewed and rehearsed regularly. Equipment and consumables should be inspected with due attention paid to storage conditions and expiry dates.

The key elements for planning and readiness to administer FWB are knowledge and rehearsal of two SOPs: Blood Donor Pre-Screening (Appendix B) and Emergency Whole Blood Drive (Appendix C).

- A contingency plan should be developed for collecting, storing, and transfusing FWB in MASCAL situations or when it may be deemed that the current blood inventory will be exhausted prior to re-supply (e.g., when multiple type-O trauma casualties are exhausting the type-O RBC inventory).
- The physical donation site should be organized in such a way as to maintain the integrity of the screening and donation process, and to minimize the possibility of clerical errors. This is especially important in emergency situations involving more than one casualty.
- Every effort should be made to adhere to the same screening, drawing, labeling, and issuing standards required for U.S. FDA-approved blood products.

- Pre-screened donors in the WBB Program determined to be suitable should be utilized, to the greatest extent possible, before using personnel who: (1) have been pre-screened or donated in the past but do not have current (within 90 days) screening and infectious disease testing; (2) have no pre-screen or donation history. All donors must be rescreened at the time of donation.
- Use LTOWB donors if available. Otherwise, upon determining the ABO/Rh status of the casualty, activate the WBB Program, re-calling pre-screened donors with the same ABO/Rh using the TMDS>Manage Donor>View Donor List, if available, or other record keeping systems. All donors should have their ABO/Rh verified (i.e. Eldon card or laboratory testing) at the time of donation. Titers for LTOWB donors should be obtained pre-deployment, which should be no more than 12 months prior to donation. The ABO and RhD group should be the same as that on the dog tag and records. Before any FWB is transfused, rapid infectious disease testing (i.e. HIV, HBV, HCV) of donor specimens shall be performed, to the greatest extent possible.
- Retrospective samples must be sent to a licensed laboratory for FDA-approved testing, regardless of whether the rapid infectious disease testing is performed pre- or post-transfusion, as these tests are not licensed for donor testing.
- Upon the notification of confirmed positive infectious disease results, a medical provider or preventive medicine personnel will be notified to ensure that the donor is notified and counseled. Donors and unit commanders must understand the importance of donor tracing.
- If a patient receives a confirmed positive infectious disease unit, the AJBPO will notify the Armed Services Blood Program immediately to initiate patient notification and an evaluation of both the donor and patient.
- In accordance with HA Policy 10-002, Policy on the Use of Non-U.S. Food and Drug Administration, recipients of FWB shall receive follow-up advice and infectious disease testing as soon as possible, and at 3-, 6-, and 12-months post-transfusion.
- Procedure. See Appendix B enclosure: ASBP 572–EWB (Emergency Whole Blood).
- Only one unit of FWB should be collected per donor. In situations where there are a limited number of donors and a dire need for blood, no more than two units may be taken from a donor. Performance decrements may occur after two-unit collections and volume resuscitation of the donor may be necessary. Collection of more than one unit per donor should only be considered under extreme circumstances and these should be thoroughly documented.

WB PEDIATRIC CONSIDERATIONS

WB has been administered to pediatric patients in recent conflicts.[25] WB has not been rigorously studied in pediatric trauma resuscitation, but has been shown to reduce blood loss and transfusion requirements in pediatric cardiac surgery.[11]

There are no established clinical criteria for administration of WB in bleeding pediatric patients. Physiologic variables should be interpreted by age (e.g. hypotension = systolic blood pressure < 70 + 2*age in years).

For patients <40kg, WB should be delivered in “unit doses” of 10-15 ml/kg. WB is more readily volume-titrated than component therapy. There are no known contraindications to using WB in pediatric casualties.

A massive transfusion in children is defined as 40 ml/kg (total blood volume is approx. 70-80ml/kg).[25]

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

1. All patients who receive blood product transfusion within 3 hours of injury
2. All patients who meet criteria for blood transfusion (severe traumatic injury (ISS ≥16 and ≥ 2 body regions injured with AIS severity ≥ 2 AND SBP < 100 OR HR > 100 OR hematocrit < 32% OR pH <7.25 within 3 hours of injury)

INTENT (EXPECTED OUTCOMES)

1. LTOWB is used for prehospital resuscitation of casualties with life-threatening injuries and hemodynamic instability (HR > 100 or SBP < 100).
2. For the population of interest, the first resuscitation fluid given after injury is a blood product, ideally cold-stored LTOWB.

PERFORMANCE / ADHERENCE METRICS

1. The number and percentage of patients in the population of interest who receive WB transfusion prior to arrival at first role of care.
2. Number and percentage of patients in population of interest who received a blood product as the first resuscitation fluid.
3. Number and percentage of patients in population of interest who received cold-stored LTOWB as the first resuscitation fluid.

DATA SOURCE

- Patient Record
- DoD Trauma Registry
- Blood transfusion databases

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Chief and JTS PI Branch.

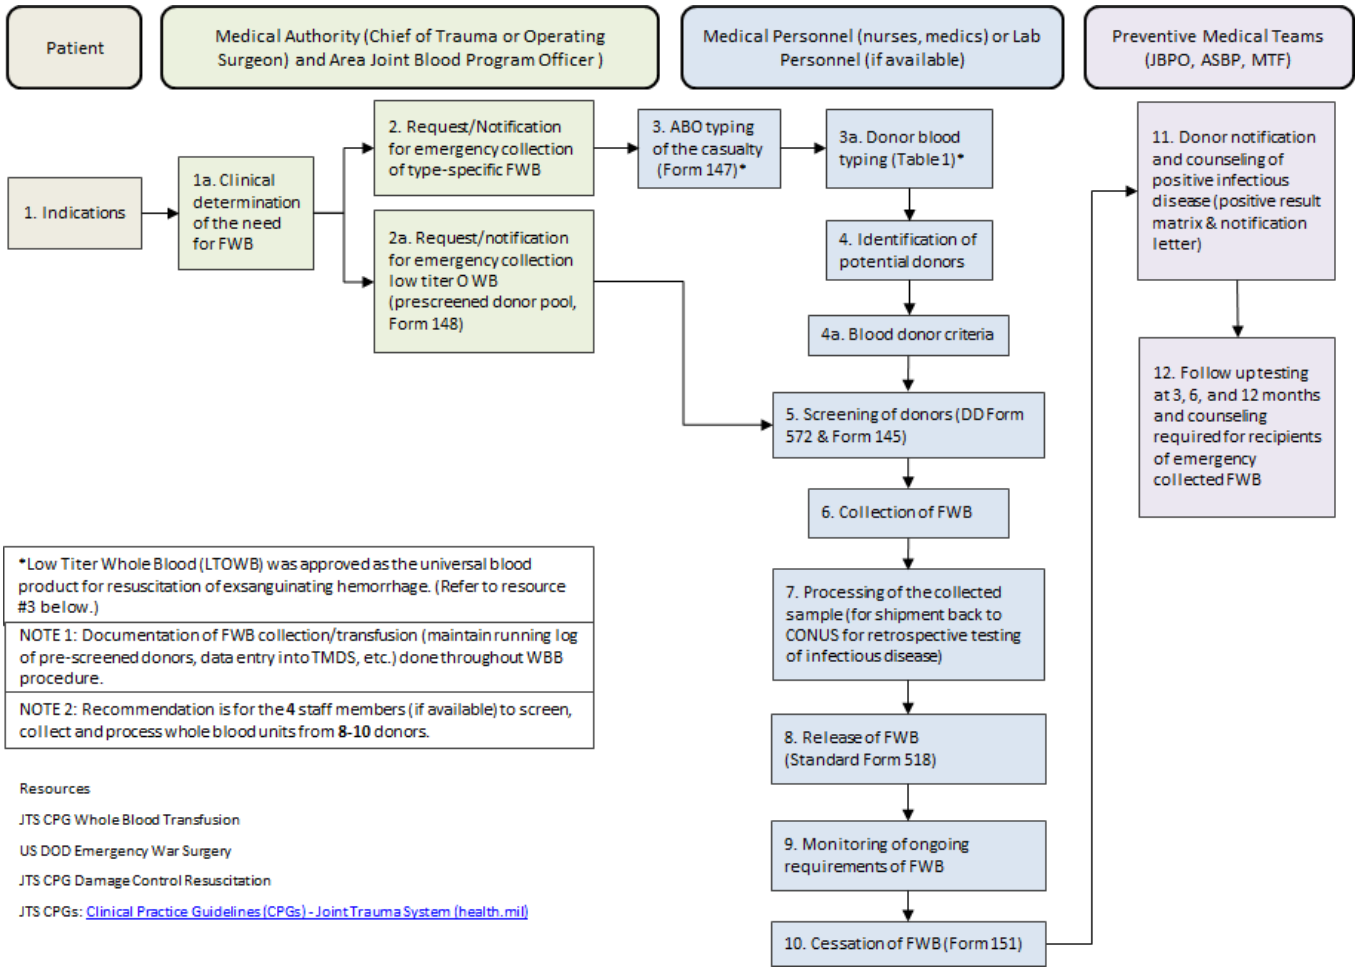
APPENDIX A: WALKING BLOOD BANK PROCESS MAP



Patient
Medical Authority (Chief of Trauma or Operating Surgeon) and Area Joint Blood Program Officer)
Medical Personnel (nurses, medics) or Lab Personnel (if available)
Preventive Medical Teams (JBPO, ASBP, MTF)
1. Indications
1a. Clinical determination of the need for FWB
2. Request/Notification for emergency collection of type-specific FWB
2a. Request/notification for emergency collection low titer O WB (prescreened donor pool, Form 148)
3. ABO typing of the casualty (Form 147)*
3a. Donor blood typing (Table 1)*
4. Identification of potential donors
4a. Blood donor criteria
5. Screening of donors (DD Form 572 & Form 145)
6. Collection of FWB
7. Processing of the collected sample (for shipment back to CONUS for retrospective testing of infectious disease)
8. Release of FWB (Standard Form 518)
9. Monitoring of ongoing requirements of FWB
10. Cessation of FWB (Form 151)
11. Donor notification and counseling of positive infectious disease (positive result matrix & notification letter)
12. Follow up testing at 3, 6, and 12 months and counseling required for recipients of emergency collected FWB
*Low Titer Whole Blood (LTOWB) was approved as the universal blood product for resuscitation of exsanguinating hemorrhage. (Refer to resource #3 below.)
NOTE 1: Documentation of FWB collection/transfusion (maintain running log of pre-screened donors, data entry into TMDS, etc.) done throughout WBB procedure.
NOTE 2: Recommendation is for the 4 staff members (if available) to screen, collect and process whole blood units from 8-10 donors.

APPENDIX B: BLOOD DONOR PRE-SCREENING SOP

Blood Donor Pre-Screening Standard Operating Procedures

This Standard Operating Procedure (SOP) accompanies the Whole Blood Transfusion Clinical Practice Guideline published by the Joint Trauma System, the DoD Center of Excellence for Trauma.

1.0 Material and Equipment

Use the following:

- ASBP 572- Emergency Whole Blood (EWB)
- Clip Boards
- Gloves
- Testing Collection Set: premade bags with 2x2 gauze, 2 red top tubes, 4 purple top tubes,
  Note: More tubes may be required if using short draw or small volume tubes
  Note: Gold/yellow top (serum separator) tubes may be substituted for red top tubes.
  Note: Pearl top (plasma preparation) tubes may be substituted for 3 of the purple top tubes.
- Blood Collection Needles
- BD Vacutainer Hubs
- Coban
- Assigned Pre Screen ISBT Labels (500 number series)
- Sharps Containers
- ABO/Rh Testing Card (e.g., Eldon Military Kit or other FDA-approved device)
- Centrifuge
- Disposable Pipettes
- Plastic Aliquot tubes/lids 13X100mm (or 12X75mm)
- Para-Film
- Biohazard Bags
- Trash Bags
- Leak Resistant Chucks
- Disposable Lab Coats
- Cold Packs
- Test Tube Racks

2.0 Records/Forms

- ASBP 572-EWB, Form 147, Form 148
- Theater Medial Data Store (TMDS), Blood Portal

3.0 Quality Control

- If possible, perform quality check on ABO/Rh Testing Card (See package inserts for procedures).
- Medical personnel should be trained by blood donor center/Blood Support Detachment or other qualified personnel.

4.0 Procedure

Pre-screening of a prospective emergency whole blood donor pool is mandatory. Development of a pre-screened donor pool should be considered a commander's priority when preparing for deployment and/or after arrival into theater. It is imperative that a donor pool once established is maintained because of the frequent redeployment of units out of theater and change of assigned personnel. Due diligence in establishing a pre-screened whole blood donor pool will decrease the risk of transmitting infectious disease while simultaneously increasing the efficiency of the whole blood collection process.

1

Perform the following steps when pre-screening donors:

1. Prepare for donor pre-screening event

Coordinate with appropriate units/contacts for times and location of event. May need to conduct a site survey to ensure appropriate site (i.e. space, lighting, privacy for interview). Samples need to be sent to the testing lab/donor center/blood support detachment as soon as possible after collection, so prior coordination with transport assets is a must.

2. Conduct the pre-screening event

- **Medical history**: Provide prospective donor an ASBP 572-EWB– ensure demographic info is legible and as complete as possible.
- **Interview**: Trained medical personnel will need to determine if the donor is eligible to donate based on the information collected.

  ***NOTE**: ONLY GROUP A questions (1-8) on the ASBP 572-EWB must be completed by the donor for pre-screening.*

- If/Then Scenarios
  a. **If:** Response to question 1 is "Yes" AND Responses for questions 2-8 are "No"
  Then: Document acceptability of Group A question responses on ASBP 572-EWB and proceed to step 3

  b. **If:** There are any "Yes" responses for questions 2-8 AND/OR Response to question 1 is "No"
  Then: Document the reason for the "Yes" response (questions 2-8) or "No" response to question 1. Defer the donor and document unacceptability of Group A question responses on ASBP 572-EWB.

3. Phlebotomy

a. Collect 4 Purple Top and 2 Red Top tubes and label with small Pre-Screen (500 number series will be used in theater) ISBT labels (without barcodes).

b. Apply the same ISBT label number to the ASBP 572-EWB. If no ISBT labels available, label tubes with donor's full name and DoD ID.

4. Register donor in TMDS per Manage Donations/Donors
See steps below in section 5.0 Maintain Database (TDMS)

***Note**: **Rapid Infectious Disease Testing is not required for the pre-screen of donors.** If performed, see Emergency Whole Blood Collection SOP for instructions.*

5. Perform ABO/Rh Testing

a. Utilizing blood from purple top tube, perform ABO/Rh confirmation using Eldon Card or other FDA-approved method to verify ABO listed on ASBP 572-EWB. (Refer to package inserts and approved facility/unit SOPs for further instructions).

b. Record Lot # of reagents, EXP Date and Results on Form 147.

c. Record blood type in TMDS.

6. Process Samples for Shipment & Testing

a. Centrifuge 2 Red Top and 3 Purple Top Tubes for 5 minutes at 4000 RPM.

b. Label three aliquot (pour off) tubes with corresponding ISBT Labels with small barcodes. Position the ISBT label vertically toward top of tube as shown at left. Write "Serum" on one tube and "Plasma" on the other two tubes. If ISBT labels are not available utilize the Donor's DoD ID or other unique identifier as appropriate to label the pour off tubes.

c. Place plasma from 3 Purple Top tubes into the 2 aliquot tubes labeled "Plasma". *3ml sample requirement per aliquot.

d. Place serum from 2 Red Top tubes into the 1 aliquot tube marked as "Serum". Do not fill over ¾ full to allow for expansion from freezing

e. The seal of capped aliquot tubes should be reinforced with para-film wrap and placed into a biohazard shipping bag or rack. If a rack is not used, rubber-band tubes from the same donor together. Repeat for each series.

f. Record sample and donor demographic data on Form 148 (Shipping Manifest). Include a printed copy of manifest with shipment and e-mail to donor center, BSD or designated facility, if possible.

g. Maintain the (pre-screening) ASBP 572-EWB at your site until the potential donor redeploys. As soon as possible ship samples and Form 148 in a blood box (Collins Blood Box) with ice bag(s) to your respective blood detachment or designated receiving facility. E-mail a copy of manifest to BSD or designated facility, if possible, and call to alert about incoming shipment.

***NOTE*: *Samples may be** *frozen until they can be shipped to a designated laboratory to perform FDA-approved testing. Contact COCOM Joint Blood Program Office (JBPO) for guidance on specimen acceptability requirements.*

***NOTE:** *Depending on pre-screening unit location and prior coordination, it may be possible to ship specimens directly to a testing or processing facility without performing the tube centrifugation and sample pour offs. Prior coordination MUST be made with COCOM JBPO or testing facility to ensure samples will remain viable if centrifugation step above will be skipped.* All donor tubes MUST be centrifuged and serum/plasma removed from RBCs within 72 hours of collection.

h. The BSD or designated unit/facility will send all samples to designated laboratory for FDA-approved testing. BSD or designated facility will enter results in TMDS and forward to submitting Role 2 or Role 3 upon completion. In some cases, the submitting Role 2 or Role 3 may have to enter results into TMDS if not supported by a BSD.

***NOTE**: The prospective donor is NOT considered pre-screened and fully qualified for FWB donation until negative or non-reactive testing results are received from a testing facility. Once confirmatory testing is received back from the testing facility and results entered into TMDS, the donors are prescreened and eligible for donation and can be verified utilizing TMDS.*

NOTE: *Testing for type O donors may include anti-A and anti-B titer testing. The titer testing must be coordinated with the testing facility prior to sample shipment. Donor should not be used as a universal type O whole blood donor until titer results verify low titer status.*

i. Any positive testing that is received by BSD or unit will be forwarded to Preventive Medicine Consultant or available Provider (MD, DO, PA, NP) to ensure proper donor care and follow-up is initiated. At no time will laboratory staff notify donors directly regarding positive testing results.

5.0 Maintain Database (TMDS)

1. Transfer demographic information from the modified ASBP 572-EWB and Form 147 to Donor Management Database in TMDS. This will act as a deferral list or an eligible donor list when a whole blood drive is necessary. It is recommended that a hard copy of Donor Database and deferral list be printed monthly (or at some regular interval) for use during Emergency Whole Blood Collection when computer assets are unavailable. Information in database must be kept confidential.

   NOTE: Ensure TMDS user is logged into TMDS under the correct blood facility account. For TMDS account guidance, contact the COCOM JBPO.

2. To enter demographic data into TMDS, go to the Manage Donation tab and select Donate Product. Enter the Donor SSN, first name, last name in appropriate fields and click NEXT.

3. In Demographic information area, enter donor's ABO/Rh, nationality and branch. Military unit and contact instructions may also be entered in the demographic information fields. Enter donor's redeployment date if known along with further contact information. In the Donation information area, enter the pre-screen date, document status of ASBP 572-EWB completion, donor's ABO/Rh and Donor Identification Number (DIN). Click ADD PRODUCT(S).

   Note*: If any of the TMDS auto-populated information fields in demographic information area is incorrect, contact the JBPO or TMDS Help Desk for guidance. TMDS contact information can be found on the TMDS log-in screen.*

   Note*: The Donation Location field information will be auto-populated within TMDS.*

4. In product description field, enter E9999V00 – PRE-SCREEN. In the expiration date field, enter date 90 days from today and click Add Product.

5. Verify donation ID, product description, product type, ABO/Rh and expiration date are correct, then click NEXT.

6. Carefully Re-verify all demographic data that populates on the screen, then click Confirm Donation. Prospective donor is now entered in TMDS.

7. From Manage Donation tab, select Update Donation. Enter donation ID number and click NEXT.

8. Enter ABO/Rh test result and date tested from Form 147 under Rapid Testing Results. In "Samples sent to" field, select BSD or unit from pull down menu and enter date samples were sent out from your facility. Now click Update Tests.

9. To register another donor, select Donate Product under Manage Donation tab and repeat process above.
10. Once pre-screen donations have been created utilizing the process above, a re-deployment date must be entered to ensure the active donor list will auto-update upon donor's exodus from theater. To accomplish this, select Manage Donor from beneath Manage Donor tab. Enter donor SSN and click Next. Select re-deployment date from the calendar tool in the "Update Re-deployment Date" field and click Update Donor. Once the displayed entry is confirmed to be correct, click Confirm Update. TMDS will now remove donor from active donor list on the re-deployment date that was entered.
11. BSD or designated unit will populate donor testing results and forward to submitting facility. Donor alerts will also be activated by BSD or unit, as necessary. This data, once populated, will be the basis by which potential donors will be deemed fully qualified for Fresh Whole Blood (FWB) donations, should the need for a Walking Blood Bank (WBB) arise at your facility.

NOTE: *In some cases, the submitting Role 2 or Role 3 may have to enter results into TMDS if not supported by a BSD.*

NOTE*: Investing time and care into building a donor pool will make performing whole blood drives easier and safer when the time comes. Your donor pool does not need to be enormous. 50 people covering most of the blood types (O, A, B) is ideal for most locations.*

Remember whole blood must be transfused group specific or from a group O/low titer donor.

Group A Questions (ALL DONORS Must Complete)

1	Have you read and do you understand the educational materials provided to you?	Y	N	5	Have you ever received money, drugs, or other payment for sex?	Y	N
2	Have you ever used needles to take drugs, steroids, or anything not prescribed by your doctor?	Y	N	6	Have you ever had cancer, heart problems, bleeding conditions, or lung disease?	Y	N
3	Have you taken any of the medications listed on the back of this form within the timeframes shown? If Yes, write medications here: _____	Y	N	7	Have you ever had hepatitis, or have you ever taken medication for treatment or exposure to hepatitis?	Y	N
4	Have you ever had a positive test for the HIV/AIDS virus?	Y	N	8	Have you ever had Malaria, Chagas or Babesiosis?	Y	N

Interviewer: Document review and eligibility below for walking blood bank (WBB) and/or low titer group O whole blood (LTOWB) donor program.

DONORS: If you are being **prescreened** for a WBB or LTOWB program, **STOP!!** Answer no more questions and sign at the bottom.
If you are here to donate a unit of blood, proceed to **Group B Supplemental Questions** and then sign at the bottom.

Group A responses acceptable (all no except Q1)? Y N ***Interviewer (initials):	All disease tests negative? Y N	Eligible for WBB? Y N	Titer Result (If group O): _____ (accept if < 256)	Eligible for LTOWB? Y N	Approving Official	Low Titer ID Issued? Y N NA

Comments:

Group B Supplemental Questions (Complete if Donating a Unit of Blood Today)

9	Are you feeling healthy and well today?	Y	N	18	In the past 12 months, have you lived with or had sex with a person who has hepatitis?	Y	N
10	Female donors: Have you ever been pregnant or are you pregnant now?	Y	N	19	In the past 12 months, have you had a transplant (such as organ, tissue, or bone marrow) or graft (such as bone or skin)?	Y	N
11	Female donors: Have you had sexual contact with a male who had sexual contact with another male in the past 12 months?	Y	N	20	In the past 12 months, have you had sexual contact with anyone who has HIV/AIDS or has had a positive test for the HIV/AIDS virus?	Y	N
12	Male donors: In the past 12 months, have you had sexual contact with another male?	Y	N	21	In the past 12 months, have you come into contact with someone else's blood?	Y	N
13	Are you currently taking malaria prophylaxis?	Y	N	22	In the past 12 months, have you had an accidental needle-stick?	Y	N
14	Are you currently taking any medications for an infection?	Y	N	23	In the past 12 months, have you had a blood transfusion?	Y	N
15	Have you had physical contact with someone who was vaccinated for smallpox in the past 8 weeks?	Y	N	24	In the past 12 months, have you had sexual contact with anyone who takes money or drugs or other payment for sex?	Y	N
16	In the past 48 hours, have you taken aspirin or anything that has aspirin in it?	Y	N	25	In the past 12 months, have you had or been treated for syphilis or gonorrhea?	Y	N
17	In the past 8 weeks, have you donated blood, platelets, or plasma?	Y	N	26	In the past 12 months, have you had sexual contact with anyone who has ever used needles to take drugs or steroids, or anything not prescribed by their doctor?	Y	N

I verify that I have answered the questions honestly, I had an opportunity to ask questions, I consent to donating blood today, and I feel my blood is safe to be transfused. If I am donating a unit of whole blood today, my blood will NOT be tested for viral diseases prior to transfusion due to the emergency situation. If for any reason I feel that my blood may not be safe, I will not donate today.

_____ _____

Donor's Signature *Date*

ASBP 572-EWB (Emergency Whole Blood), 5 Apr 2018

ASBP 572: Emergency Whole Blood (back)

DONOR EDUCATIONAL MATERIAL

Blood donation is a voluntary process requiring the collection of approximately 450-500 mL of blood. The usual collection time ranges from 5 to 10 minutes. Complications at the venipuncture site may include, but are not limited to: discomfort, bruising, swelling, or infection. Other complications could occur during or after your donation such as: fatigue, light-headedness, dizziness, nausea, vomiting, and/or fainting. On very rare occasions, a more severe reaction may occur.

MEDICATION LIST: Donors **SHOULD NOT** discontinue medications prescribed by their physician in order to donate blood. Certain medications in your system can cause harm to some patients if your blood is transfused. If your last dose of the following medications was taken within the timeframe listed, you should not donate today nor should you participate in a walking blood bank program because the medication has not cleared from your system.

Prescreen or Donating Blood Today:

Erivedge, Odomzo	Soriatane	Bovine Insulin, Human Growth Hormone, Tegison
2 years	3 years	**EVER** in your life

Donating Blood Today (must screen donor for drugs below AND list above if donating whole blood):

Eliquis, Feldene, Fragmin, Lovenox, Pradaxa, Savaysa, Xarelto		Arixtra, Brilinta, Coumadin, Effient, LMW Heparin, Jantoven, Warfilone	
2 days		7 days	
Plavix, Ticlid, Zontivity	Absorica, Accutane, Amnesteem, Claravis, Myorisan, Propecia, Proscar, Sotret, Zenatane	Avodart, Jalyn	Experimental Meds/Vaccines
14 days	1 month	6 months	1 year

Your signature on the other side of this form acknowledges that you understand the questions and this educational material and that you agree to not donate any blood products if you are at risk of transmitting Human Immunodeficiency Virus (HIV) or any other virus. We know that you would not donate unless you think your blood is safe. However, in order for us to assess all risks that may affect you or a patient receiving a transfusion, it is essential that you answer each question completely and accurately on the other side of this form. If you do not understand a question, ask a staff member. All information you provide is confidential. It is critical that you alert your unit provider or medic if any of your responses change or if you have any concerns about the safety of your blood. This will facilitate notification and follow up testing for the recipient if needed.

Your blood will be tested for several types of viral markers including Hepatitis B, Hepatitis C, HIV, syphilis and other infections. You will be notified about any positive test result which may disqualify you from donating in the future, and your name will be entered onto a list of permanently deferred donors. If testing does not occur (due to specimen acceptability) or if testing results are not clearly negative or positive, your name may be placed on a deferral list without you being informed until the results are further clarified. For active duty personnel and reservists, positive screening and confirmatory results will be forwarded to appropriate medical personnel for further evaluation and "fitness for duty" determination (if required).

HIGH RISK BEHAVIORS:

Certain diseases such as HIV/AIDS and hepatitis can be spread through sexual contact OR by sharing drug needles/syringes. These viruses can enter your blood stream and can be transmitted to another person who is transfused with your blood, plasma, or platelets. Sexual contact includes: Vaginal contact (contact between penis and vagina), oral sex (mouth or tongue on someone's vagina, penis, or anus), and/or anal sex (contact between penis and anus). **YOUR BLOOD CAN TRANSMIT DISEASES,** including HIV/AIDS, even if you feel well and all your tests are normal. This is because even the best tests cannot detect the virus for a period of time after you are infected.

DO NOT DONATE IF YOU:

- Have AIDS or have ever had a positive HIV test
- Have ever used needles to take any drugs not prescribed by your doctor
- Are a male who has had sexual contact with another male in the past 12 months
- Have ever taken money, drugs or other payment for sex
- Have had sexual contact in the past 12 months with anyone described above
- Have had syphilis or gonorrhea in the past 12 months
- Have been in juvenile detention, lockup, jail or prison for more than 72 consecutive hours in the past 12 months

DO NOT DONATE TO GET A TEST! If you think you may be at risk for HIV/AIDS or any other infection, do not donate simply to get a test. See your medical provider to obtain an HIV/AIDS test. The following symptoms can be present before an HIV test turns positive: fever, enlarged lymph glands, sore throat, and/or rash.

NOTIFY YOUR UNIT MEDIC OR UNIT PROVIDER IF:

- Anything changes that would cause a different response to a question
- If you think your blood may not be safe for another person to receive
- If you become sick within 14 days after donating a unit of blood

THANK YOU FOR DONATING BLOOD!

ASBP 572-EWB (Emergency Whole Blood), 5 Apr 2018

APPENDIX C: EMERGENCY WHOLE BLOOD COLLECTION SOP

Emergency Whole Blood Collection Standard Operating Procedures

Purpose: This Standard Operating Procedure (SOP) accompanies the Whole Blood Transfusion Clinical Practice Guideline published by the Joint Trauma System, the DoD Center of Excellence for Trauma.

1.0 Materials and Equipment

Use the following materials and equipment as applicable

- Vitals Machine
- Blood Collection Beds
- Stethoscope
- Blood Pressure cuff
- Digital Thermometer and/or Tempadots
- Lancets
- POCT Hemoglobinometer
- Electronic table top scale (optional)
- Alcohol Pads
- Coban
- Blood Bags (CPDA-1 or CPD)

  ***NOTE**: If an additive solution (AS) bag is present with a multiple bag set-up, the AS SHALL NOT be added to the whole blood.*
- Blood Trip Scale with 585±2g trip counter-weight and QC weights or HemoFlow.
- Testing Collection Set: premade bags with sterile 4x4 gauze, Chloraprep, 2 red top tubes, 4 purple top tubes

  ***NOTE**: Gold/yellow top (serum separator) tubes may be substituted for red top tubes.*

  Note: Pearl top (plasma preparation) tubes may be substituted for 3 of the purple top tubes.
- ChloraPrep
- Adapter Luer
- ABO/Rh Testing Card (e.g., Eldon Military Kit or other FDA-approved device)
- 4x4 Gauze
- Adhesive Tape
- Hemostats
- Gloves
- Tourniquet
- Rapid HIV, Malaria, HBsAg, and HCV test kits
- Serological RPR kit
- Plastic Aliquot tubes/lids
- Parafilm
- Clinical Rotator
- Centrifuge
- Disposable Pipettes
- Scissors
- Strippers
- Metal Clips
- Biohazard Container/ Sharps Container
- Whole Blood ISBT Labels (100 number series)

OR

- **Fresh Whole Blood Collection Set**

(Donor & Recipient Modules) contains all items above (or alternatives), other than those shaded gray

1

2.0 Records/Forms

- Forms required:
- Modified ASBP 572-EWB
- Form 145
- Form 147
- Form 148
- Form 150A
- Form 150B
- Form 151 and SF 518 (as applicable)
- Theater Medical Data Store (TMDS)
- Blood Portal

3.0 Quality Control (QC)

- Perform QC on POCT Hemoglobinometer
- Perform QC on ABO/Rh Testing Card, RPR, HCV, HBsAg, HIV, and Malaria Kits (See package inserts and local SOPs for procedures.)
- Medical personnel should be trained by blood donor center/Blood Support Detachment or other qualified personnel.

4.0 Procedures

Perform the following steps when a physician requests whole blood units:

1. **Permission to Conduct the Blood Drives**

   - Notify Role 2/3 Commander, DCCS and Laboratory OIC/NCOIC that a physician is requesting whole blood for transfusion.
   - Once the Commander/DCCS/Medical OIC grants permission, initiate the emergency whole blood collection. Notify the Area Joint Blood Program Officer that facility is performing whole blood collection. Trained medical personnel should oversee the process.

2. **Donor Recruitment**

   - When emergency whole blood collections are required, donors will be selected in the following order, in descending priority:

     a. Donors who have been prescreened within the last 90 days with the full panel of FDA-licensed donor infectious disease tests and found to be negative for all tests.
     NOTE: *Any donor with a positive test result will not be listed as an approved, prescreened donor and must not be collected.*

     b. Donors who have been prescreened between 90 days and 365 days with the full panel of FDA-licensed donor infectious disease tests and found to be negative for all tests.

     c. Donors who report being repeat blood doors in the past and have not been deferred for transfusion-transmitted disease.

     d. Donors who have not been prescreened with FDA-licensed tests, nor have been blood donors in the past.

- To the maximum extent possible:
  a. Blood will only be collected from United States personnel to include military members, DoD civilians or contractors, or beneficiaries.
  b. Blood may be collected from pre-screened coalition partner forces if screening program has been reviewed by the JBPO and deemed acceptable by the COCOM Surgeon and the ASBP. Note, screening results must be available to the JBPO.
  c. On the day of donation, prospective donors will be screened for eligibility using approved donor history screening protocols and be tested for infectious diseases using ASBP-approved rapid screening tests. As much as possible, rapid screening tests should be performed before issuing the product.
- Low titer Group O Whole Blood (LTOWB) donors have been tested and found to have anti-A/anti-B antibody titers of <1:256 (recorded in TMDS). LTOWB collected from these donors may be given to a recipient of any ABO type during damage control resuscitation.
- Non-LTOWB FWB donors must be an ABO type-specific match to the casualty. If not matched, a fatal hemolytic reaction may occur. Casualty ABO/Rh type must be determined (by using rapid ABO/Rh card or laboratory testing) before conducting type-specific FWB collection.

3. **Pull a pre-screened donor list from TMDS: Manage Donor>View Donor List.**
4. **Select filters**
   a. Select filters for ABO/Rh of the potential whole blood recipient if using type-specific FWB, Screened (select ALL), Alert (select ALL), COCOM (select applicable).
   b. Highlight your facility in the Available Facilities tab and click Add.
   c. Once your facility appears in the Search Facility box, click Display Donor List.
   d. The potential donor list for the blood type required will now appear on the screen.

   ***NOTE**: If searching for LTOWB pre-screened donors, use same process above except select O pos and O neg in the ABO/Rh selection area.*
5. **Verify donor**

The donor ABO/Rh must be verified (by rapid ABO/Rh card or laboratory testing) prior to transfusion even if donor is in TMDS with pre-screening results.

5.0 Donor and Testing Area Preparation

1. Set up blood donor beds.
2. Perform QC on weighing device if available, (i.e., HemoFlow or Trip Scale).

   ***NOTE:** If no trip scale is available, see section below Whole Blood Collection: Set up the whole blood collection bag.*

3. Ensure the necessary equipment to perform donor screening, testing and collection are available. (See WBB Supply List with NSNs)

6.0 Perform Donor Screening

1. To the greatest extent possible, potential whole blood donors should be selected from among the pre-tested and qualified population documented in TMDS. This is the best practice to mitigate the risk to the recipient of Transfusion Transmitted Diseases (TTD) and hemolytic reactions.
2. Give donor ASBP 572-EWB and instruct donor to complete demographic information and to answer questionnaire by circling "Yes" or "No". While donor is completing questionnaire, screen for donor alerts and completed FDA test results in TMDS (deferrals).
3. Locate donor's name on the Donor List displayed in TMDS. To the left of their name, click View. If all TTD results are Negative (within last 90 days) and there are no Donor Alerts, then the Donor is deemed fully Pre- Screened/Tested. To minimize risk to the recipient, it is recommended that pre-tested population be exhausted prior to resorting to collections from the untested population.
4. A qualified interviewer will review the ASBP 572-EWB for completeness and donor suitability criteria following steps below.

   If/Then Scenarios

   IF: Responses for questions 1 and 9 are "Yes" AND Responses for questions 2-8 and 10-26 are "No"*
   THEN: Proceed to step 5 for donor temperature.

   IF: Response to question 1 or 9 is "No" AND/OR There are any "Yes" responses for questions 2-8 or 10-26*
   THEN: Document the reason for the "Yes" response (questions 2-8 or 10-26) or "No" response (questions 1 or 9). Defer the donor.

   ****NOTE**: For question 13, if the donor is required by the Chain of Command to take malaria prophylaxis due to deployed location, then response should be "Yes". If donor answers "No" despite being required to take prophylaxis, then donor should be deferred unless all other suitable donors are unavailable.*

5. Perform and record temperature on the ASBP 572-EWB.

   If/Then Scenarios

   IF: ≤99.5 ºF or 37.5 ºC
   Then: Proceed to the next step.
   IF: >99.5 ºF or 37.5 ºC
   Then Stop the donation process. The donor is "Ineligible" at this time.

6. Perform and record measurements of donor pulse and blood pressure on the ASBP 572-EWB.

   IF: Systolic BP is 90-180
   Diastolic BP is 50-100
   Pulse is 50-100 bpm

   THEN: Proceed to step 7 for donor hematocrit.

IF: Systolic BP is <90 or >180
Diastolic BP is<50 or >100
Pulse is <50 or >100
THEN: Stop the donation process. The donor is "Ineligible" at this time.

7. Perform and record hematocrit/hemoglobin results on ASBP 572-EWB, if possible.

If/Then Scenarios

IF: Male: ≥13.0 g/dL
Female: ≥12.5 g/dL
THEN: Proceed to next step.

IF: Male: <13.0 g/dL
Female: <12.5 g/dL
THEN: Defer donor and stop the donation process. The donor is "Ineligible" at this time.

8. Donor is physiologically acceptable to donate, have the donor sign the ASBP 572-EWB and proceed to next step.

9. A competent medical authority should review the ASBP 572-EWB to determine the eligibility of the donor.

IF/Then Scenarios
IF: Acceptable.
THEN: Donor is "Eligible," proceed to Step 10.

IF: Unacceptable.
THEN: Donor is "Ineligible," stop donation process and document deferral as appropriate in TMDS.

10. Issue blood bag and test collection set to donor. Label bag and ASBP 572-EWB with Whole Blood ISBT labels. Blood collection tubes (2 red top 4 purple top) should be labeled with the corresponding small ISBT labels (without barcode). See Illustration to the left. If no labels are available, bags and all samples should be labeled with donor's full name and DoD ID or Blood Bag Segment Number.

7.0 Whole Blood Collections

1. Seat donor in blood donor table or reclining chair. Ask the donor their name and verify donor demographic information is correct on the ASBP 572-EWB. Verify also that the labels on the blood bag, sample tubes, and ASBP 572-EWB correctly correspond to each other and the donor.

NOTE: *If a discrepancy is noted, STOP and correct before proceeding further.*

2. Apply the tourniquet to the arm that will be used for phlebotomy.
   - Have donor grip their hands or a squeezable object
   - Palpate the antecubital area of the arm in order to locate a suitable vein
   - Remove the tourniquet

Note: *The vein of choice must be large enough for venipuncture using a 16-gauge needle and straight enough to accommodate at least one-fourth of the needle length*

3. Utilizing ChloraPrep, remove applicator from package; do not touch applicator tip.

4. Holding sponge tip down, pinch barrel of applicator to release antiseptic and wet sponge tip by pressing and releasing the sponge against the treatment area until liquid is visible on the skin.

5. Use gentle back-and-forth strokes over the 3 inch treatment area for 30 seconds and then allow area to dry for 30 seconds. Do not blot or wipe away antiseptic.

   NOTE: *It is not necessary to use the entire amount of the solution in the applicator*

6. Set up the whole blood collection bag.

   - Ensure that the donor's ISBT Label or ID has been recorded in the Unit Number field on the CPD Whole Blood Collection bag if not previously performed.
   - Ensure date is recorded in the "Today's Date" field under the Group B questions.

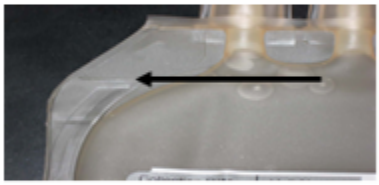
   Inspect the bag and tubing for cuts, kinks, discoloration or any kind of damage and discard bag if present.

7. Set-up trip scale (Manual or Electronic). Perform quality control, if possible, to obtain a counter-weight of 585 grams.

   NOTE: *If no trip scale is available, the Terumo Single Blood Bag (CPDA-1) can be filled with whole blood to the mark pictured below. It is however recommended that weight then be checked with table top scale (if available)*

   The target weight for 450 mL is 585 grams.

   Do not use if overfilled as blood clots may develop from an incorrect ratio of whole blood to anti-coagulant causing potential harm to the patient.



8. Using a hemostat, clamp tubing between the needle and the main bag. This will prevent air contamination of blood after the needle cover is removed. Place tape within reach for anchoring the needle during phlebotomy.

   NOTE: *Place a loose knot in the tubing approximately 6 inches from the needle prior to uncapping needle, if metal seal clips and hand crimpers are not available.*

9. Apply tourniquet with enough pressure. If using a blood pressure cuff adjust to approximately 40-60 mm Hg.

10. Twist off the needle cover and inspect the needle for barbs or other defects.

11. Pull the skin taut below the venipuncture site.

12. With the bevel up, hold the needle at the hub, at approximately a 30-45 degree angle and pierce the skin with a smooth, quick thrust at the selected point of entry.

13. When the bevel is completely under the skin, lower the angle of the needle to approximately 10º or less and, with a steady push, advance needle to penetrate the vein wall. Thread needle approximately ½ inch inside the vein to maintain a secure position and to lessen the chance of a clot forming.

14. Release the hemostat clamp on the collection bag tubing and observe the blood flow through the tubing and into the collection bag.

    IF/THEN Scenarios

    IF Blood flow is impeded
    THEN: Try adjusting the needle with least discomfort without hurting the donor.

    IF: Blood flow is still impeded
    THEN: Seek assistance from another phlebotomist before discontinuing the phlebotomy.

15. Fill sample tubes using tube adapter if available. After filling sample tubes, gently rock tubes to mix contents and verify once again that donation identification number on tubes corresponds to donation identification number on the collection bag and the ASBP 572-EWB.

    NOTE: *If no tube adapter available on whole blood bag tubing, fill sample tubes by performing a venipuncture phlebotomy on the arm not used for whole blood bag donation.*

16. Instruct donor to relax their grip and to rhythmically squeeze every 5 to 10 seconds, relaxing between squeezes.

17. Secure the needle to the donor's arm with tape, across the hub or on the tubing near the hub of the needle. This will optimize the positioning of the needle to prevent rotation of the needle or drag on the tubing, which may impede blood flow. An additional piece of tape may be placed across the tubing lower on the arm.

18. Partially reduce the pressure by loosening the tourniquet or blood pressure cuff to approximately 20-40 mm Hg. Mix blood bag several times during the collection to prevent clotting.

19. Cover the phlebotomy site with sterile gauze dressing, to keep the site clean and needle out of view. Lift the gauze occasionally to monitor for a hematoma.

20. If a hematoma is evident, remove tourniquet and needle from donor's arm and place sterile gauze square over the hematoma and apply firm digital pressure while donor's arm is held above the heart level.

21. Record the following in the appropriate blocks on the ASBP 572-EWB:

    - Time phlebotomy was started
    - Initials of the phlebotomist

22. Watch for the signal of a filled unit by monitoring for the completion indicator of the weighing device or visual reference point (see step 6), if not using a weighing device. Record stop time on the ASBP 572-EWB.

    NOTE: *A 10 inch piece of 5-50 cord/nylon cord may be used to check for unit fill. As bag fills, place cord around middle/center of bag and continue to monitor until both ends of the cord wrap around the bag and touch.*

23. Seal the tubing 1 to 2 inches below the "Y" segment of the tubing using a metal seal slip and a hand crimper (or pulling tight the loose knot in the tubing).

24. Grasp the tubing on the donor side of the seal and press to remove a portion of blood in the tubing. Crimp the tubing at this spot. Cut the tubing between the two seals.
25. Remove tourniquet or blood pressure cuff and tape strips from donor's arm.
26. Place the fingers of one hand gently over the sterile gauze. DO NOT APPLY PRESSURE OVER THE NEEDLE. With the other hand, smoothly and quickly withdraw the needle. Apply firm pressure to the phlebotomy site.
27. Instruct donor to apply firm pressure over the gauze. Encourage donor to maintain a relaxed elevated position, rather than tensing the muscle. This precaution will minimize the bleeding into the venipuncture area.
28. Secure the dressing with Coban or similar bandage wrap. Observe the donor for an appropriate length of time after the donation for any signs of an adverse event.
29. Discard the needle assembly into a sharps container.
30. Using a hand stripper/crimper, strip all blood from the tubing into the primary collection bag. This should be done ASAP after collection. (Stripping is pushing the blood in the tubing into the blood filled bag with the rollers on the stripper/crimper device)
31. Mix contents in the primary collection bag. DO NOT strip the tubing and allow tubing to refill without mixing. Release the stripper and allow the anti-coagulated blood to reenter the tubing. Perform this procedure three times.

8.0 Process Donor Units

1. Take donor unit and donor sample tubes (2 red top tubes, 4 purple top tubes) to processing area.
2. Strip donor units segment tubing three times and mix, so as to avoid the development of clots.
3. Perform ABO, Rh type utilizing ABO/Rh Testing Card and purple top tube. Record results on Form 147.
4. Write the donor blood type on the bag (ABO/Rh Testing Card) along with date, time and phlebotomist initials of collection.
5. If whole blood unit is drawn from a low titer donor, "Low Titer for Anti-A/Anti-B" should be written on the label or use a sticker with the same verbiage.
6. Write the expiration date of the unit on the label, which is 24 hours from collection if stored at room temperature. If placed into refrigerated storage within 8 hours of collection, the unit may be stored for 21 or 35 days depending on anticoagulant. JBPO approval is required for storage of whole blood unit for longer than 24 hours.

   NOTE: *CPDA-1 units have a 35 day expiration / CPD units have a 21 day expiration*
7. Create product in TMDS while Rapid Testing is being performed.

   NOTE: *Rapid tests should be performed and found to be negative prior to transfusion, to the greatest extent possible. In situations requiring whole blood, available blood component inventory should continue to be transfused in lieu of whole blood until rapid testing has been performed and found to be negative.*

9.0 Create Whole Blood Units in TMDS

1. From Manage Donation tab, select Donate Product.
2. Enter the Donor SSN, first name, last name in appropriate fields and click NEXT.
3. In Demographic information area, enter donor's ABO/Rh, nationality and branch. Military unit and contact instructions may also be entered in the demographic information fields. Enter donor's redeployment date if known along with further contact information. In the Donation information area, enter the pre-screen date, document status of ASBP 572-EWB completion, donor's ABO/Rh and Donor Identification Number (DIN). Click ADD PRODUCT(S).

   NOTE: *If any of the TMDS auto-populated information fields in demographic information area is incorrect, contact the JBPO or TMDS Help Desk for guidance. TMDS contact information can be found on the TMDS log-in screen.*

   NOTE: *The Donation Location field information will be auto-populated within TMDS.*
4. Enter product code E0053V00 for whole blood collected in CPDA-1 anticoagulant or E0009V00 for whole blood collected in CPD anticoagulant.
5. Enter the expiration date of the unit, which is 24 hours from collection if stored at room temperature. If placed into refrigerated storage within 8 hours of collection, the unit may be stored for 21 or 35 days depending on anticoagulant. JBPO approval is required for storage of whole blood unit for longer than 24 hours.

   NOTE: *CPDA-1 units have a 35 day expiration / CPD units have a 21 day expiration*
6. Click Add Product.
7. Verify donation ID, product description, product type, ABO/Rh and expiration date are correct, then click NEXT.
8. Re-verify all demographic and unit data then click Confirm Donation.
9. Repeat steps 1-8 for each product collected.

10.0 Pre-Transfusion Rapid Testing

1. Rapid tests should be performed and found to be negative prior to transfusion, to the greatest extent possible. In situations requiring whole blood, available blood component inventory should continue to be transfused in lieu of whole blood until rapid testing has been performed and found to be negative.
2. Centrifuge 2 Red Top and 3 Purple Top Tubes for 5 minutes at 4000 RPM.
3. Perform Rapid ABO/Rh using whole blood from 4th purple top tube and record results on Form 147.
4. Perform HBsAg, HCV, HIV, and Malaria using whole blood from 4th purple top tube. Perform RPR using serum from centrifuged red top tube. Testing should be performed IAW Test Kit package inserts and local SOP. Record reagent Name, Lot #, Exp Date, and Results on Form 145.
5. Upon completion of rapid tests with negative results, whole blood unit may be issued for transfusion.

6. When time allows, rapid test results need to be entered into TMDS. To do this click on Update Donation under the Manage Donation tab.

11.0 Issue and Manage Whole Blood Inventory

1. It is recommended that some sort of blood product issue document (ex., SF 518) be utilized to account for the issue of Whole Blood from the laboratory. WBB operations are at times chaotic and do not often allow for real-time updates of TMDS.
2. Provider requesting Fresh Whole Blood should sign Emergency Release Letter of understanding Form 150a or 150b as appropriate. Forms should be maintained in patient transfusion records.
3. Accurate dispositions of all Whole Blood units collected MUST be properly dispositioned in TMDS. Every unit must be created, transfused, expired or destroyed as appropriate.

12.0 Process Samples for Shipment and Testing

1. Label three aliquot (pour off) tubes with corresponding ISBT Labels with small barcodes. Position the ISBT label vertically toward the top of tube. Write "Serum" on one tube and "Plasma" on the other two tubes. If ISBT labels are not available utilize the Donor's DoD ID or other unique identifier as appropriate to label the pour off tubes.
2. Place plasma from 3 Purple Top tubes into the 2 aliquot tubes labeled "Plasma". *3ml sample requirement per aliquot.
3. Place serum from 2 Red Top tubes into the 1 aliquot tube marked as "Serum".

   Do not fill over ¾ full to allow for expansion from freezing
4. The seal of capped aliquot tubes should be reinforced with para-film wrap and placed into a biohazard shipping bag or rack. Repeat for each series
5. Record sample and donor demographic data on Form 148 (Shipping Manifest). Include a printed copy of manifest with shipment and e-mail to BSD or designated facility, if possible.
6. Form 151- Whole Blood Transfusion Checklist must be submitted with shipment for every unit of whole blood transfused.
7. Send copies of ASBP 572-EWB for each unit collection along with Form 145, Form 147 and Form 148 in a blood box (Collins Blood Box) with ice bag(s) to your respective blood detachment or designated receiving facility. E-mail a copy of manifest to BSD or designated facility, if possible, and call to alert about incoming shipment. Ensure originals of all forms remain at collecting location.
8. **Samples may be** frozen until they can be shipped to a designated laboratory to perform FDA-approved testing. Contact COCOM Joint Blood Program Office (JBPO) for guidance on specimen acceptability requirements. Depending on collecting unit/facility location and prior coordination, it may be possible to ship specimens directly to a testing or processing facility without performing the tube centrifugation and sample pour offs. Prior coordination MUST be made with COCOM JBPO or testing facility to ensure samples will remain viable if centrifugation step above will be skipped.
9. All donor tubes MUST be centrifuged and serum/plasma removed from RBCs within 72 hours of collection. The BSD or designated unit/facility will send all samples to designated laboratory for

FDA-approved testing. BSD or designated facility will enter results in TMDS and forward to submitting Role 2 or Role 3 upon completion. In some cases, the submitting Role 2 or Role 3 may have to enter results into TMDS if not supported by a BSD.

NOTE: *Testing for group O donors may include anti-A and anti-B titer testing. The titer testing must be coordinated with the testing facility prior to sample shipment.*

NOTE: *The results of this testing will be viewed as a pre-screen for donor's next donation.*

10. Any positive testing that is received by BSD or unit will be forwarded to Preventive Medicine Consultant or available Provider (MD, DO, PA, NP) to ensure proper donor care and follow-up is initiated. At no time will laboratory staff notify donors directly regarding positive testing results. JBPO will be notified of positive results to ensure recipient notification is completed for transfused units.

BLOOD OR BLOOD COMPONENT TRANSFUSION
Medical Record

STANDARD FORM 518 (REV. 9-92)
Prescribed by GSA/ICMR, FIRMR (41 CFR) 201-9.202-1

Standard Form 518-123: Blood or Blood Component Release (instructions)

INSTRUCTIONS FOR NON SELF-EXPLANATORY ITEMS

SECTION I – REQUISITION

Component Requested

"Other (Specify)" – List any whole blood or blood product not on menu, i.e., washed RBC's deglycerolized RBC's, etc.

"Volume Requested (If applicable)" – Use only when different from standard amount, i.e., exchange transfusion 50 ml.

"Known Antibody Formation/Transfusion Reaction" – Check Medical Records. Annotate N/A if appropriate.

"If Patient is Female, Is There History Of" – Check medical records. Annotate N/A if appropriate.

SECTION II – PRE-TRANSFUSION TESTING

"Transfusion Number/Patient Number" – List either based on local procedures.

"Previous Record Check" – Current tests should be compared with prior records for ABO and Rh type, difficulty in blood typing, clinically significant unexpected antibodies, and severe adverse reactions.

"Test Interpretation" – Use the following standard notations. "NEG or "POS" for antibody screen block. "COMPAT" or "INCOMPAT" for crossmatch block.

SECTION III – RECORD OF TRANSFUSION

"Pre-Transfusion Data"

"Inspected and Issued by _____ at _____ on _____."
(Signature) (Hour) (Date)

This statement is to be completed by the issuing laboratory person once he/she has inspected the blood immediately before issue from the laboratory. The blood must not be abnormal in color or appearance or expired, and if any of these conditions exist the blood will not be used for transfusion.

"Signature" blank must contain the signature, as opposed to name, of issuing laboratory person.

"Hour" and "Date" are as of actual issue.

The issuing laboratory person will secure this form to the blood bag by string, rubberband, or tie knotted to the tag and the blood container before issuing the blood.

"Post-Transfusion Data" – Completed by transfusionist.

"Amount Given _____ ml" – Visual approximation.

"Description of Reaction" – Check appropriate reaction or describe "other" on separate sheet, if necessary, and attach to SF 518.

"Other Difficulties"– Check item or describe on separate sheet and attach to SF 518.

APPENDIX D: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Acute Traumatic Wound Management in the Prolonged Field Care Setting (CPG ID: 62)

The intent of this guideline is to provide evidence- and experience-based solutions to those who manage both simple and complex wounds in an austere environment.

INTRODUCTION

This Role 1, prolonged field care (PFC) guideline is intended for use after Tactical Combat Casualty Care (TCCC) guidelines when evacuation to higher level of care is not immediately possible. A provider must first be an expert in TCCC. The intent of this guideline is to provide evidence- and experience-based solutions to those who manage both simple and complex wounds in an austere environment. Emphasis is placed on the basics of wound care, using the tools most familiar to a Role 1 provider. Ideal hospital techniques are adapted to meet the PFC environment while still maintaining the highest standards of care possible.

SPECIAL CONSIDERATIONS IN AUSTERE ENVIRONMENT

Specific considerations for wound care in the PFC context: although all 10 of the PFC core capabilities should be implemented,[1] the following have areas of emphasis specific to longer-term wound care and management.

- **Physical examination:** Techniques specific to prolonged wound management include inspection of the wound and surrounding skin for evidence of necrosis or infection, passive and active range of motion to assess level of disability, ultrasound to assist in evaluating critical anatomy and/or guide regional anesthesia, distal pulse trending to assess for vascular compromise, and laboratory studies as an adjunct to determine the amount of blood loss or look for evidence of a developing infection.
- **Nursing:** Scheduled dressing changes are necessary to ensure proper wound healing and infection management. The bandage plan should include scheduled changes, materials to be used, as well as analgesia.
- **Surgical intervention:** Efforts are most likely geared toward irrigation and debridement. They should be scheduled and planned with evacuation timeline or inability to evacuate taken into consideration.
- **Telemedicine:** Should be initiated as early as possible so the consultant can properly guide the patient's management and monitor the patient's status. Photographs play a vital role in a consultant's ability to advise the Role 1 provider on wound care, especially in the assessment of viable tissue.

TYPES OF WOUNDS

- **Abrasion**: A wound created by scraping or wearing away of the skin. These are partial-thickness wounds.
- **Burn**: A wound created by thermal or chemical destruction of the skin and underlying tissues. These can be partial- or full-thickness wounds. Management of burn wounds is addressed in a separate guideline.
- **Puncture**: A wound caused by a narrow object and results in a relatively small skin opening relative to the depth.
- **Laceration**: A deep cut or tear in the skin.
- **Gunshot**: A wound caused by a bullet; involves a high transfer of energy and extensive damage to tissues.
- **Blast**: A complex wound that may involve penetrating fragments, extensive tissue damage or loss, and massive contamination with dirt and debris.
- **Crush injury**: A wound caused by blunt trauma and may include injury to skin, muscle, or bone.

The overall principles of wound management are the same for each type of wound. The size of the wound and the evacuation timeline, as well as resources available and level of training of the medical provider, will influence the wound management plan. In most cases, open wounds with contamination, devitalization, loss of tissue (skin, muscle, or bone), or infection will require a more complex treatment strategy because of the invasive nature of the wound, especially in the context of war wounds. Large abrasions still require careful cleansing and dressing with a high index of suspicion for skin infection. Careful evaluation of the wound should lead to development of a problem list in the event PFC will be required. The care provider should focus on anesthesia, debridement and irrigation, wound dressing, antimicrobial therapy, scheduled dressing changes, and pain control. In select cases, delayed primary closure (DPC) may be considered.

ANALGESIA

Goal: Irrigating, debriding, repairing, and bandaging wounds can be painful for the patient. Analgesia is often necessary to facilitate wound care and sedation may be required for more severe wounds.

- **Best**: Regional nerve block (for extremity wounds, ONLY if fully trained and equipped); and/or ketamine drip augmented with versed IV push as needed.
- **Better**: Local anesthetic and/or ketamine drip augmented with versed IV push as needed.
- **Minimum**: Local anesthetic and/or any pain medication.

    1. 1% or 2% lidocaine (with or without epinephrine)
    2. Oral (i.e., by mouth [PO]) acetaminophen and meloxicam
    3. PO acetaminophen/oxycodone (e.g., Percocet; Endo Pharmaceuticals, http://www.endo.com)
    4. Oral transmucosal fentanyl
    5. IV/IM ketamine
    6. IV morphine, hydromorphone, or fentanyl

Local anesthetic notes:

- For smaller wounds that require painful interventions, direct injection of local anesthetic into the wound margins with 1% or 2% lidocaine can provide enough analgesic effect for the patient's comfort.
- The maximum dose of lidocaine WITHOUT epinephrine is 3mg/kg (1% lidocaine has 10mg/mL and 2% lidocaine has 20mg/mL).
- The maximum dose of lidocaine WITH epinephrine is 7mg/kg (1% lidocaine has 10mg/mL and 2% lidocaine has 20mg/mL).
- Epinephrine injected with lidocaine has several properties that are advantageous: reduces bleeding, increases the duration of the local anesthetic effect by at least 50% depending on the site, and raises the maximum dose.
- Injection of epinephrine-containing anesthetics should be used with caution in the tip of the nose, ear, penis, fingers and toes, because of possible risk of ischemia.

- Buffering lidocaine with sodium bicarbonate using a 9:1 ratio (9mL lidocaine with 1mL bicarbonate), keeping the lidocaine at room temperature, and using smaller gauge needles can lessen the burning sensation associated with injection.
- Sodium bicarbonate buffers the acidity of local anesthetics, allowing for a more rapid analgesic onset.
- If properly trained and equipped with an ultrasound machine, the provider can perform ultrasound-guided regional blocks for those wounds in which local anesthesia will not manage the pain effectively during wound care. See Analgesia and Sedation CPG for PFC.
- For wounds that require the patient to be on a surgical plane, see Analgesia and Sedation CPG for PFC.

See the Analgesia and Sedation CPG for PFC for a more comprehensive summary.

IRRIGATION

Goal: Because war wounds are most often grossly contaminated, proper irrigation techniques should be implemented as early as possible after wounding to reduce the possibility of infection. Pressure, fluid choice, and fluid amount are the tenants of irrigation: the solution to pollution is dilution.

- **Best**: Irrigate wounds with Dakin's solution or sterile isotonic solution.
- **Better**: Irrigate wounds with clean, potable tap water.
- **Minimum**: Irrigate wounds with the cleanest water available (nonpotable water should be boiled for a minimum of 3 minutes and then cooled to body temperature).

Irrigation notes:

- Cleansing the entire patient (shower or cloth bath) will reduce the risk of infection.
- Bacterial loads drop significantly with increases in wound irrigation fluid volumes.[2]
- Evaluate the wound size and contamination level to determine the optimal amount of irrigation: 1–3L for small or clean wounds, 4–8L for intermediate or dirty wounds, and ≥9L for large or very dirty wounds.
- Dakin's solution (0.025%) may be used for irrigation of large, very dirty, or infected wounds to help treat wound infection and prevent fungal infection. A diluted concentration of one-tenth the strength of "half-strength" Dakin's solution has been shown to be toxic to microorganisms without damaging tissues. The recipe is given below.[3–5]

  Half-strength Dakin's Solution

  1. 1L water, sterile or boiled
  2. 5mL household bleach (5.25% hypochlorite solution, unscented)
  3. Sodium bicarbonate: 1.5mL (1/2 tsp) of baking soda or 4 ampules (200mL) of 8.5% sodium bicarbonate injection (preferred, but can leave out if not available)
  4. Once mixed, Dakin's solution can be stored. The half-strength solution should be diluted 1:10 with water for wound irrigation solution.

- Additives such as iodine, bacitracin, or alcohol are not associated with reduced infection.[6]
- Very high-pressure (>15 psi) irrigation is not associated with reduced infection and has been associated with tissue damage and injection of bacteria deeper into the tissues.[7] For smaller wounds, a large-bore catheter on the end of a syringe will provide high-pressure (6–15 psi) flow and is the ideal pressure for maintaining tissue viability and irrigation in a contaminated wound.[8] A 19-gauge catheter with a 35mL syringe will deliver approximately 8 psi. For moderate sized wounds, a bulb syringe or bottle with puncture holes in the top can be used for low pressure (<6 psi) irrigation. For large wounds, bags of IV fluids can be connected to IV tubing to facilitate large-volume irrigation or any large container may be used to pour water onto the wound while gently scrubbing the wound.[9]
- Debris made of wood, vegetative material, clothing, and any debris in the foot should be excised and/or removed if possible; however, foreign bodies penetrating into vital structures, including the eye, should be left in place until the patient can reach a surgical capability. Most retained metal fragments do not need to be removed, particularly if doing so creates additional tissue damage.

DEBRIDEMENT

Goal: Removal of devitalized tissue and debris reduces both infection and morbidity. Devitalized tissue acts as a medium for bacterial growth and inhibits leukocyte function. The goal is to remove this tissue while preserving as much perfused tissue as possible. A basic knowledge of debriding skills—cutting, clamping, grasping, ligation, and tying—allows the provider to effectively manage the balance between salvageable and unsalvageable tissue.

Identification of viable tissue may be challenging. Tissue that is clearly dead should be removed, whereas tissue of uncertain viability should be preserved and re-examined in 24–48 hours. Use the four Cs, along with clinical judgment, when excising muscle tissue: color, contraction, consistency, and circulation.

***Caution**: Debridement of large wounds or wounds associated with other injuries will result in significant blood loss. Be prepared to give blood transfusion.*

- **Best**: Use an assistant; remove nonviable tissue using sharp dissection (sterile scalpel or scissors) and control bleeding using tourniquet, topical hemostatic dressings, direct pressure, clamping, suture ligation, and/or electrocautery. Questionably viable tissue may be retained with repeat debridement once every 24–48 hours until arrival at surgical facility.[10]
- **Better**: Remove nonviable tissue using sharp dissection (sterile scalpel or scissors) and control bleeding using tourniquet, topical hemostatic dressings, direct pressure, clamping, and/or suture ligation. Repeat debridement or delayed primary closure in 3–5 days.
- **Minimum**: When unable to evacuate and resources for serial debridements are not available, remove all nonviable and questionably viable tissue, using sharp dissection (clean blade or scissors) and control bleeding with tourniquet and/or direct pressure. Leave clean dressing in place, then perform delayed primary closure in 4–7 days if no sign of infection.[11,12] See Appendix A for further details on the International Committee of the Red Cross (ICRC) method of wound care.

DEBRIDEMENT NOTES

Exposure

- Deeper wounds should be exposed through generous skin incisions in the long axis of the extremity.
- Avoid exposing major blood vessels, tendons, and nerves, unless they are injured.

Anatomic Considerations

- Review the anatomy of the injured body part before debridement. Extremity wounds are by far the most common and the need for reference anatomic diagrams should be anticipated.
- If a major blood vessel is injured, it will require ligation, repair, or shunting. In the extremity, ligation may result in amputation; however, vascular repair or shunting are advanced surgical skills.
- Damaged parts of tendons do not need much debridement and should be preserved when possible. Tendons may be repaired later as a delayed procedure.
- Damaged nerves should not be debrided. Some nerves may be repaired as a delayed procedure.
- Loose, unattached fragments of bone should be removed; however, any bone fragments still attached to muscle should be left in the wound. After debridement and dressing placement, a fractured extremity should be immobilized with a splint.
- After debridement, attempt to ensure that vital structures (i.e. blood vessels, nerves, tendons, bone) are covered with soft tissue. This may require partial wound closure or mobilization of soft tissue to cover the structure.
- Mangled extremities may require amputation. Amputation is best left to a surgical facility and the wound kept as clean as possible while awaiting evacuation. If evacuation is not possible, amputation may be necessary.
- An injured extremity may require fasciotomy. Be vigilant for signs of compartment syndrome.
- Wounds penetrating the chest cavity should not be probed and should be minimally debrided to avoid creating a pneumothorax. If a pneumothorax is present, a chest tube should be placed through a separate, clean skin incision.
- Wounds penetrating the abdominal cavity require abdominal exploration (i.e. laparotomy) if associated with hemodynamic instability or peritonitis. Otherwise, these wounds may be debrided and dressed as any other wound.
- Small wounds or puncture wounds can be managed using local anesthesia, washing (scrubbing) the wound with soap and water or disinfectant soap, irrigating, dressing, and then allowing the wound to close by secondary intent. Some minor excision of the wound edges may be indicated.
- Large wounds require careful attention to hemostasis, wound care, and consideration for repeat debridements or delayed closure.

Complex wounds are best managed with a telemedicine consultation. Photos or video of the wound should be transmitted.

Assessment of Tissue Viability

- Color is the least reliable trait for measuring tissue viability. Evaluate the tissue's color relative to similar tissue deemed viable. Nonviable tissue appears pale, bluish, gray, or black. Bruised tissue that is viable may also have a dark coloration.
- Contractility refers to the retraction of muscle tissue when tension is placed on it by grasping. Nonviable muscle tissue does not contract.
- Consistency evaluation involves comparing potentially dead tissue with live tissue in terms of texture, density, and rigidity. Viable tissue has elasticity and firmness, whereas nonviable tissue is friable and/or is in a state of liquefaction.
- Circulation may be the best indicator of salvageable tissue because any tissue that bleeds when very minor trauma is applied can almost always be judged as perfused and, therefore, viable.

Debridement Techniques

- **Cutting**: Meticulous sharp surgical technique using scalpel and scissors should be the starting point for almost all war wounds that involve penetrating foreign bodies. Typically, #10 or #15 scalpel blades (or #11, as an alternative) are used for the removal of skin tissue, and sharp scissors (e.g., Metzenbaum, Mayo) are used for the removal of deeper tissues below the dermis.
- **Grasping**: Forceps, such as the Adson, Rat Tooth, and DeBakey, are used for grasping and tissue manipulation to fully explore a wound.
- Ideally, equipment used for debridement should be sterile. However, if this is not available, disinfected or clean instruments will suffice (see Appendix B for nonstandard tool sterilization/disinfection).

Hemorrhage Control Techniques

Consideration for hemorrhage control should be given before starting debridement. For larger areas of debridement to an extremity, place a tourniquet before debridement. Elevate the extremity before tourniquet placement to facilitate venous return and reduce bleeding. Monitor the tourniquet times closely and attempt to keep the total tourniquet time <90 minutes.

- **Direct pressure** to a wound, preferably in combination with a hemostatic dressing, will stop most minor bleeding encountered during wound care.
- **Hemostatic dressings** should be applied along with direct pressure for a minimum of 3 minutes. At times, up to 10 minutes of direct pressure may be required.
    - **Basic hemostatic dressings** include Combat Gauze (Z-Medica; www.z-medica.com/healthcare), Celox gauze (Med-trade Products; http://www.celoxmedical.com), ChitoGauze (HemCon Medical Technologies, http://www.hemcon.com), and Surgicel (Johnson & Johnson, https://www.jnj.com).
    - **Advanced hemostatic agents** include FloSeal (Baxter Healthcare, http://www.floseal.com) and Evarrest (Johnson & Johnson, http://www.ethicon.com), among many others.
- **Clamping bleeding vessels** provides a temporary hemostatic maneuver. When applying a clamp, try to avoid crushing the surrounding tissues. The bleeding vessel can then be ligated and tied off. Clamps can be left on for an extended time, if necessary.

- **Ligatures/sutures** provide a definitive treatment. Use of a silk suture is generally sufficient, although other materials can be used as well (Appendix C). For smaller structures, either 3-0 or 4-0 suture is sufficient, whereas larger structures may require 0 or 2-0 suture.

- **Electrocautery** stops bleeding by burning the tissue. It is available as either a battery-powered, hand-held device or a larger portable device. This can be used to cauterize bleeding vessels up to 3mm in diameter. The bleeding site should be identified, the ends coapted between a pair of forceps or clamps, and electricity then applied. If the cautery device is used to "paint" the surface, this results in damage to surrounding tissues.

> ***Caution**: Aggressive debridement may cause uncontrollable bleeding. Do not debride an area larger than can be controlled with direct pressure or a tourniquet. Observe closely for bleeding for at least 1 hour after debridement.*

- **Debridement** is not a singular event.[10] War wounds often require multiple debridement procedures as the body physiologically responds and the wound evolves. When adequate resources are available, a patient's wound should be evaluated every 24 hours, or as often as the clinician deems necessary. When resources are very limited, the ICRC approach has been successfully used to limit interventions to an initial D&I with application of a bulky absorbent dressing.

DRESSINGS

Goal: Quality dressing application focuses on keeping wounds clean, absorbing drainage, debriding fibrinous exudate from the wound surface, and increasing the speed of healing.

Shallow Wounds or Abrasions

- **Best**: dressing tailored to the specific type of wound Abrasions: Apply antibiotic ointment (e.g., Bacitracin or Silvadene) to the skin, place a non-adherent dressing over the area (e.g., Adaptic [KCI, http://www.acelity.com] or Telfa [Medtronic, http://www.medtronic.com]), and cover with an absorbent gauze dressing (e.g., Kerlix [Medtronic]). This should be repeated daily.

  - Alternative: Silverlon (Argentum Medical, http://www.silverlon.com) can be applied directly to a clean wound and covered with a gauze dressing. Moisten outer gauze dressing with water or normal saline daily. Replace Silverlon every 3–5 days (can remove and clean with water and reuse for up to 5 days). The outer gauze can be changed as needed if it becomes saturated with exudate or otherwise dirty. If the patient develops any evidence of infection, the Silverlon must be removed and the wound inspected sooner than 3–5 days.

  - Puncture wounds or small open wounds: Apply an absorbent gauze dressing over the area and change as needed when it becomes saturated with exudate or otherwise dirty, or at least once every 24 hours.

  - Small, clean lacerations: may be sutured, or Dermabond (Johnson & Johnson, http://www.ethicon.com) can be applied to the skin to adhere the wound edges together. Ensure that the Dermabond is applied to the skin, not to the deeper tissues. If Dermabond is used to close the wound, this will also suffice as a dressing.

- **Better**: Apply any available sterile gauze dressing.

- **Minimum**: Apply any available clean dressing.

Deep or Large Open Wounds

- **Best**: Negative pressure wound therapy (NPWT)
  - Commercially available kits such as the KCI Wound vacuum-assisted closure (V.A.C. Therapy, KCI, http://www.kci-medical.com) device can be used to both cover the wound and promote wound healing.[13] For exposed soft tissue, the pressure is usually set at 75–125mmHg of continuous suction.
  - Field-expedient wound VAC devices can be improvised from gauze, Tegaderm or Ioban, and suction tubing hooked up to a suction device (Appendix D).
  - NPWT dressings are generally changed every 2–3 days. Although they can be left in place for a longer time, the degree of granulation that can occur after 3 days generally leads to some bleeding with their removal.
  - NPWT dressings placed over infected wounds should be changed daily, along with wound debridement and irrigation, until the infection is controlled.
- **Better**: Wet-to-dry dressing
  - Wet-to-dry dressings can be created using either a sterile isotonic fluid or clean water, if there is no sterile fluid available. A gauze dressing should be moistened (not soaked) and applied to all open, exposed tissues and loosely packed into the wound cavities. An absorbent gauze dressing or Army Battle Dressing pad is placed over top to absorb any extra fluids or exudate. This may be secured with tape or wrapped with a gauze bandage roll or elastic bandage.
  - Removal of dressings from a wound provides its own form of mechanical debridement; exudate adheres to the bandages and is then pulled from the wound during changing. Inspect old bandages during a dressing change for signs of infection by observing the color and odor of the exudate; the color should be off-white or slightly yellow, and the bandage should not smell sweet or foul. Do not moisten the gauze being removed to make the dressing change easier, otherwise the debridement effect will be lost.
  - Ideally, the dressing should be changed one or two times per day, unless the situation dictates a less frequent approach.
  - For wounds that are already draining heavily, a dry-to-wet dressing may be used instead.
- **Minimum**: Place a bulky dressing with dry gauze, absorbent padding, and elastic bandage; leave in place 4–7 days if wound is clean and without sign of infection. See Appendix A for further details on the ICRC method of wound care.

CLOSURE

Goal: In most cases, war wounds should be closed by a surgical facility, where infection can be more effectively mitigated and the wound can be explored more effectively. However, when appropriate, wound closure simplifies the overall management of the wound.

- Puncture wounds, in general, should not be primarily closed. Small wounds should be allowed to freely drain as needed and close by secondary intent. Larger puncture wounds may require debridement and irrigation, as described above.

- Lacerations with minimal tissue loss/destruction and minimal need for debridement can generally be primarily closed provided that the wound is clean, there is not significant tension with the closure, and there has been <12 hours from injury to closure (this can be extended to 24 hours for lacerations to the face or scalp).
- Lacerations that do not meet the above criteria can be considered for a DPC. These patients are provided 3–7 days of wound care to assure the wound is clean and without complications, and then is closed with either widely spaced sutures or staples.
- Undermine wound margins if needed to reverse the retracted and inverted edges, and relieve any tension to allow skin closure.
- Wounds with tissue loss or damage are generally not closed primarily. Instead, these wounds are treated with dressing changes and allowed to heal by secondary intent. However, there is occasionally a role for DPC in select wounds.
- When in doubt, it is better to leave a wound open and plan for healing by secondary intent.
- If a wound becomes infected after closure, it should be reopened and debrided to drain pus and remove infected, dead tissue.

> ***Caution:*** *Wound closure may speed healing; however, closure will also greatly increase the risk of infection. Only wounds that are very clean and have been well-debrided should be closed.*

INFECTION PREVENTION

Goal: Antimicrobial drug therapy is a critical complement to debridement and irrigation in the fight against infection. This includes prophylaxis against Clostridium tetani (the causal agent of tetanus), as appropriate.

- Guidance on specific antibacterial regimens can be found in the Joint Trauma System CPG Infection Control.
- In general, cefazolin 2g in 250 mL NS IV over 5 min every 8 hours for 24 hours is adequate for most dirty wounds of the head and neck, torso, and extremities.
- Oral antibiotics may be used: moxifloxacin 400mg PO once or clindamycin 300mg PO every 8 hours for 24 hours.
- Note: Moxifloxacin may be replaced with levofloxacin 750 mg PO daily to provide better coverage of bacteria found in wet terrain/ jungle environment.
- Ertapenem is commonly carried by Role 1 providers and gives broad-spectrum gram-positive, gram-negative, and anaerobic coverage. It is an acceptable choice when more-specific antibiotics are not available. Give 1g in 250 mL NS IV over 5 min (provides 24 hours of coverage).

If following the ICRC wound care method (Appendix A), continue antibiotics for 5 days or until DPC.

Prophylaxis against tetanus should be initiated, as appropriate, based upon the condition of the wound and the individual's immunization history.[14] (Appendix E).

INFECTION TREATMENT

Goal: If a wound develops signs of infection (e.g., increasing pain, erythema, purulent drainage) or the patient becomes systemically ill (e.g., fever, tachycardia, hypotension, lethargy, decreased mental status), wound infection must be identified and treated. Treat infected wounds with a combination of local wound care and systemic antibiotics.

- Remove all dressings and inspect wound.
- Wounds that have been closed must be reopened.
- Repeat wound debridement to drain pus and remove all dead, infected tissue. If necessary, extend the wound with an incision in the long axis of the extremity.
- Worst-case scenario may require amputation of an extremity to control life-threatening infection.
- Increase the frequency of dressing changes to once or twice daily.
- Continue antibiotics for 7–10 days, moxifloxacin 400mg PO daily, levofloxacin 750mg PO daily, or ertapenam 1g IV daily, or alternative broad-spectrum antibiotic as available (if possible, change antibiotic from prevention regimen).
- Wounds with known or suspected infections can be treated using Dakin's solution (dilute bleach) for irrigation and wet-to-dry dressing. This can be an effective adjunct, particularly for suspected fungal and Pseudomonal infections.[3,15]

Daily sugar or honey dressings for infected wounds may successfully treat infection in very austere settings.[12] This involves irrigating the wound with saline or the cleanest water available and then filling it with sugar or honey, which is left in place under a dry dressing, repeating every 24 hours.

Severe wound infection *is life threatening and may require aggressive debridement, up to and including amputation. Evacuate patient. If evacuation is not possible, obtain telemedicine consultation and initiate infection treatments above.*

SPECIAL CONSIDERATIONS

FACE AND SCALP

- These wounds rarely become infected because of the high blood flow of the face and scalp.
- Most face and scalp wounds can be closed after irrigation. Debridement should be minimized to reduce cosmetic deformity. If the patient will arrive at a surgical facility within 24 hours, it is better to defer wound closure.
- The clinician should take into consideration the low probability of infection when planning closure of a facial wound because of the poor cosmetic outcomes associated with delayed primary closure.
- When primary closure is acceptable, sutures should only remain in place for 4–5 days for the face and 7 days for the scalp.

OPEN GLOBE INJURY

- Apply an eye shield to prevent further damage.
- Do not place any type of dressing in contact with the globe or underneath the eye shield.
- Moxifloxacin 400mg PO daily to prevent endophthalmitis
- Ondansetron 4mg PO/IV every 4 hours as needed for associated nausea
- Pain control as needed (narcotics as well as ketamine are approved for use)
- Position the patient with the head elevated, if possible.
- Ultrasound evaluation is contraindicated when open globe injury is suspected.
- The best results are achieved if surgery occurs within 24 hours of injury.

ANIMAL BITES

- All animal bite treatments should begin with immediate, thorough cleaning of all wounds with soap and water.
- Most animal bites should be allowed to heal by secondary intent (especially puncture wounds).[16]
- Moxifloxacin 400mg PO daily OR Augmentin (amoxicillin/clavulanic acid; GlaxoSmithKline, http://us.gsk.com/) 875/125mg PO every 12 hours for 7 days are the best choices for most animal bites. Doxycycline (100mg PO twice a day) or clindamycin (300mg PO 3 times a day) with levofloxacin (750mg PO daily) are acceptable alternatives.
- Consider the need for rabies vaccination (Appendix E).

AQUATIC EXPOSURE

- Management of wounds exposed to fresh or salt water is unchanged; however, additional agents are occasionally required for adequate antimicrobial coverage.[17]
- Levofloxacin 750mg PO daily (second-line doxycycline 100mg PO twice daily) to cover for Aeromonas species and Vibrio species.

Given the risk of atypical infections, telemedicine consultation should be sought if the wound worsens.

CHRONIC NONHEALING WOUNDS

If a wound has not healed by 2 weeks, it is likely the result of underlying infection (consider osteomyelitis as a potential cause), inadequate tissue perfusion, or inadequate nutrition.[18] Often it is multifactorial and so more than one source needs to be addressed.

Consider telemedicine consultation if the wound is not healing.

- Packing and Planning Considerations. See Appendix F.
- Wound Management Summary Table. See Appendix G.

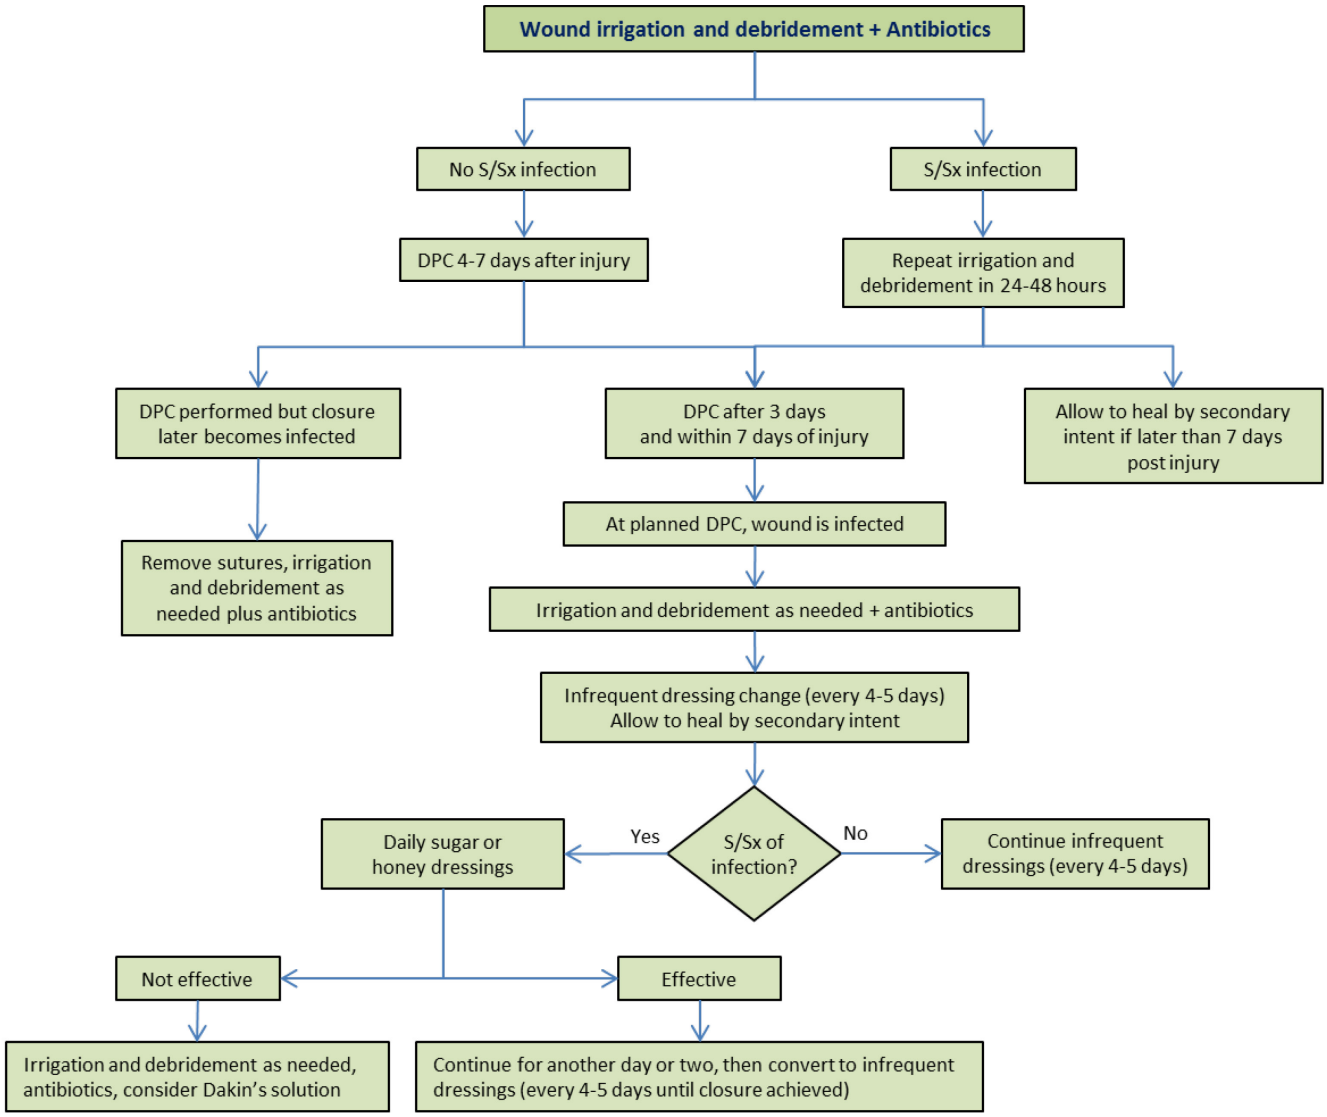
APPENDIX A : INTERNATIONAL COMMITTEE OF THE RED CROSS SURGICAL WOUND MANAGEMENT FLOW CHART



Wound irrigation and debridement + Antibiotics
No S/Sx infection
S/Sx infection
DPC 4-7 days after injury
Repeat irrigation and debridement in 24-48 hours
DPC performed but closure later becomes infected
DPC after 3 days and within 7 days of injury
Allow to heal by secondary intent if later than 7 days post injury
At planned DPC, wound is infected
Remove sutures, irrigation and debridement as needed plus antibiotics
Irrigation and debridement as needed + antibiotics
Infrequent dressing change (every 4-5 days) Allow to heal by secondary intent
Daily sugar or honey dressings
Yes
S/Sx of infection?
No
Continue infrequent dressings (every 4-5 days)
Not effective
Effective
Irrigation and debridement as needed, antibiotics, consider Dakin's solution
Continue for another day or two, then convert to infrequent dressings (every 4-5 days until closure achieved)

This pathway should be used when conserving resources is a top priority and when evacuation is not possible. DPC, delayed primary closure; S, sign; Sx, symptom.

Notes on wound care according to the ICRC method: The ICRC wound care methods are most applicable for management of war wounds in austere conditions and with limited resources that prohibit serial (follow-on) debridements with associated postoperative care:

1. Dirty environment
2. Limited supplies
3. Limited manpower
4. Limited time (mission dictated)
5. Wounds older than 24 hours
6. Inability to evacuate (includes host-nation patient care where care provided in the austere environment is the definitive level of care available)

Serial debridement every 24–48 hours is not possible in this environment. Therefore, the initial debridement must remove all tissue that is nonviable or questionably viable to remove dead tissue that may act as a culture medium. The wound is then managed with a bulky absorbent dressing that can stay in place for 4–7 days with a low likelihood of infection. Continue antibiotics for 5 days or until delayed primary closure.

Wounds that become infected or have exposed vital structures, such as blood vessels, nerves, or bone, should be treated with more frequent debridement and dressing changes.

After 4–7 days, remove the dressing and evaluate both the dressing and the wound using adequate pain control and sedation, as needed. The bandage and dressing should be dry, stained (greenish-black), and have an ammonia-like odor (good-bad odor), and the dressing should be adherent to the wound. The wound base should bleed slightly and the muscle should contract. Any small area of collagen that was not removed with the dressing can be scraped off with an instrument. This reveals a clean wound that is ready for closure.

If the wound is infected, the dressing may slide easily off the wound without resistance because there is a layer of pus between the dressing and the wound surface. The wound may contain areas of necrotic tissue and the surface of the wound is dull or greyish-red, or may give off the "bad-bad smell" of wound sepsis. Such an infected wound requires further excision and DPC is delayed or the wound is allowed to close by secondary intent. Closure by secondary intent may take several weeks. ICRC recommends a change of dry bulky gauze dressing and gentle washing with normal saline every 4–5 days for closure by secondary intent.

The ICRC dressing change algorithm for closure by secondary intent is as follows:

Question 1: Is the wound clean? **Yes:** infrequent (every 4–5 days) dressing with dry bulky gauze. **No:** continue
Question 2: Is there erythema and tenderness around the wound? **Yes**: antibiotics and continue **No**: continue
Question 3: Is there a large volume of exudate? **Yes:** daily sugar or honey dressings; this involves rinsing the wound with saline and then filling it with sugar or honey, which is left in place under a dry dressing. This is repeated after 24 hours. **No:** infrequent dressing with dry bulky gauze
Question 4: Has there been a response to sugar/honey dressings? **Yes:** Continue sugar/honey dressings or convert to infrequent dry bulky gauze. **No:** Consider antiseptic solution or further surgical debridement
If the wound exudate continues, consider exploring the wound surgically.

APPENDIX B: INSTRUMENT STERILIZATION (STANDARD AND NONSTANDARD)

DEFINITIONS

Cleaning: Removes dirt, debris, and biological material from surgical instruments

Disinfect: Cleaning with a disinfectant to destroy bacteria

Sterilize: Making free from bacteria or other living organisms

NOTES

- Cleaning, disinfecting, and sterilizing are the three levels of instrument care.
- Critical tools are those that make contact with open wounds, open vasculature, and/or organs. Semicritical tools are those that contact the mucosa, and noncritical tools are those that contact intact skin.
- Sterilization is the goal for any tools that will be used for surgical intervention; however, if life depends on it and sterilization is not an option; disinfection can be achieved using one of the options listed below as the "Better" option.
- The goal of sterilization is to eliminate the presence of bacteria, viruses, parasites, and particulates; bacterial spores are the most difficult to destroy.
- For all nonstandard sterilization techniques, gross contamination should be removed from all instruments/equipment by scrubbing with soap and water first.
- Chemical sterilization elements should never be combined.
- Steam with distilled water is the preferred sterilization technique.

BEST: Remove gross contamination, using soap and water, then sterilize by steam or dry heat using one of these techniques:

- Steam sterilization using one of the following techniques and the following temperatures: 121°C (250°F) for 30 minutes or 132°C (270°F) for 4 minutes
- Autoclave (portable or standard size) and distilled water
- Steam sterilization using the SF medical Tac-Set portable sterilizer pot (NSN: 6530-00-926-2022), according to the manufacturer's operating instructions:
    1. Remove the cover by loosening the wing nuts in a counterclockwise motion. Always undo two opposite wing nuts at a time.
    2. Lubricate the metal-to-metal seal where side wall and bevel meet on the inside of the sterilizer. Use petroleum jelly or mineral oil.
    3. Remove the aluminum inner container. Pour clean (preferably distilled) water into sterilizer to a depth of not less than three-fourths of an inch, but no more than 1 inch.
    4. Place inner container rack into inner container with the lip or edge side downward. Place articles to be sterilized on container rack. Only steam should make contact with articles. Replace packed inner container into sterilizer, ensuring the air exhaust tube channel is in position on the right side of the container when it is placed into the unit.
    5. Place sterilizer cover on unit, making sure that the index alignment arrow on the cover aligns with index line/arrow on the side of the bottom. Ensure that the flexible tube is inserted into the guide channel on the inside wall of the aluminum container. Tighten the wing nuts evenly, always tightening down two opposite nuts simultaneously to assure a proper seal.
    6. Place unit onto a heat source. Open the control valve by placing valve lever in an upright position. It is important that steam be permitted to escape vigorously for at least 7 minutes or until the flow of steam is continuous. Afterwards, close the control valve. When pressure gauge reaches 17–19 psi, reduce heat as necessary to maintain a constant pressure of 17–19 psi within the unit.
    7. The sterilization period begins when the pressure steam gauge needle registers in the green sterilization band shown on the face of the gauge (i.e., 17–21 psi). This should be no less than 35 minutes. Note: At altitudes higher than sea level, settings need to be adequately adjusted to compensate for the effect of altitude on water's boiling point. The manufacturer suggests increasing pressure by 0.5 psi for every 1,000 feet of elevation above sea level.
    8. At the end of the sterilization period, remove unit from heat source and move the lever on the control valve to an upright position to allow the steam to escape. With caution, loosen wing nuts and remove the cover to retrieve sterilized items.

DRY HEAT

- Dry heat may also be used to sterilize surgical instruments.
- Instruments can be wrapped in aluminum foil or placed in sterilization trays before putting them in the oven.
- Allow the instruments to cool to room temperature inside the oven before use or storage.
- Instruments can be heated to any of the following to be considered sterilized:
  - 180°C (356°F) for 30 minutes
  - 170°C (338°F) for 1 hour
  - 160°C (320°F) for 2 hours
  - 149°C (300°F) for 2.5 hours
  - 141°C (286°F) for 3 hours

BETTER: Remove gross contamination using soap and water, then sterilize with improvised autoclave or chemical disinfection.

- Improvised autoclave using a pressure cooker that can reach the steam sterilization temperatures listed above.
  - Place wire rack in the bottom to prevent the instruments from becoming submerged. Only steam should make contact with the instruments. Begin timing for sterilization once steam starts to vent from the pressure cooker.
  - Pressure cookers operate at various pressures and temperatures. Sterilization time of 60 minutes is recommended.
- Glutaraldehyde (Cidex©; Johnson & Johnson): Widely available and accepted as a high-quality disinfectant in healthcare facilities.
  - Can be used to sterilize aluminum, brass, copper, stainless steel, plastics, and elastomers.
  - Once the container is open, the chemical has a limited shelf life—a minimum of 14 days, usually 28–30 days; refer to the specific product's manual for the exact shelf life.
  - Test strips can indicate the efficacy of an opened container of glutaraldehyde.
  - Alkaline glutaraldehyde mixes are more effective than acidic glutaraldehyde mixes.
  - Items should be soaked for 60 minutes for maximum efficacy.
  - Long-term exposure can cause irritation to tissues; rinse tools before use.
- Formaldehyde: Prepare 5% formaldehyde solution.
  - Both metallic and plastic medical equipment can be sterilized using formaldehyde.
  - Wrap a 5mg tablet of formaldehyde in gauze and crush the tablet.
  - Place the gauze-wrapped tablet in 100mL of potable water (can be cold water).
  - This solution can be stored for up to 30 days without losing its potency.
  - Lower concentrations of formaldehyde can be used, but the amount of time the instruments are submerged in the solution needs to be increased to compensate for this change.
  - Clean the instruments with soap and water, and remove any blood and tissue.
  - Soak the instruments in the 5% formaldehyde solution for at least 1 hour but preferably for 12–24 hours.[19,20]
  - Duration should be closer to 24 hours if 1% formaldehyde solutions are used (i.e., 5mg tablet in 500mL of water).
  - The instruments and formaldehyde solution can be kept at room temperature.
  - Remove the instruments and rinse with water or saline before use.
- Alcohol: 60% to 90% minimum; tools need 3 hours of contact time. Consumable alcohol must be a minimum of 120 proof. This method is not sporicidal and, therefore, not recommended as a primary modality for surgical items.
- Sodium hypochlorite (household bleach)
  - This disinfectant is caustic to eyes, oropharynx, esophagus, and gastric tissue.
  - Undiluted (5.25%) sodium hypochlorite should be used to disinfect instruments categorized as critical.
  - Instruments should have a minimum contact time of 5 minutes.

MINIMUM: Remove gross contamination, using soap and water, then boil instruments in at least 100°C (212°F) water for at least 1 minute.

***NOTE*:** *This method does not sterilize instruments and should be used as a last resort for surgical instruments.*

APPENDIX C: SUTURE CHART

- When supplies are limited, any suture may be used for any purpose; however, as a general guideline, absorbable suture should be used to approximate tissues deep to the skin, silk may be used to ligate blood vessels, and a monofilament suture (nylon/Prolene; Johnson & Johnson) should be used for the skin.
- Most suturing/ligating can be accomplished with 2-0 sutures. Finer suture (3-0 or 4-0) may be used on the face for better cosmetic result. Heavier suture (0 or 1) may be used for DPC of larger wounds or for the scalp.
- Tapered needles are best for suturing soft-tissue layers; cutting needles are best for suturing skin; strait needles do not require a needle holder.
- Undesired tissue reactivity is greater with:
  - Multifilament (compared with monofilament)
  - Larger suture gauge
  - Natural material (compared with synthetic)
- Recommended multipurpose sutures: 2-0 Vicryl suture with CT-1 needle, 0 Prolene or Nylon with FSLX needle, 0 silk with strait needle.

Absorbable Sutures				
Suture	Effective wound support, days	Time to complete absorption, days	Comments	Usual indications
Surgical gut	8–9	30	Rarely used; high tissue reactivity	Approximate soft-tissue layers deep to the skin
Chromic gut	10–21	>90	Gut treated with chromium to decrease tissue reactivity and slow absorption	Approximate soft-tissue layers deep to the skin
Fast-absorbing gut	5–7	14–28	Gut treated with heat to speed absorption	Skin closure when suture removal will be difficult or impossible
Polyglactin (Vicryl)	21	90	Less reactive than gut; synthetic	Approximate soft-tissue layers deep to the skin
Vicryl Rapide (Johnson & Johnson)	10	42	Gamma-irradiated to speed absorption	Skin closure when suture removal will be difficult or impossible

Non Absorbable Sutures				
Suture	Tensile Strength	Tissue Reactivity	Comments	Usual Indications
Silk	Low	High	Multifilament, pliable	Ligate blood vessels
Nylon (e.g., Ethelon; Johnson & Johnson)	High	Low	Monofilament, stiff	Skin closure
Polypropylene (e.g., Prolene)	Moderate	Very Low	Monofilament, less knot security (may need extra knot)	Skin closure, repair blood vessels

Suture Removal Time Frames	
Body Part	Number of Days After Suturing
Face	4-5
Scalp	7
Chest, extremities	10-14
High tension areas, joint, back	14-21

APPENDIX D: FIELD-EXPEDIENT WOUND VACUUM-ASSISTED CLOSURE

1. Copious irrigation with debridement of necrotic tissue and removal of foreign debris.

2. Placement of gauze or reticulated sponge at base of wound.

3. Placement of suction tubing (e.g., Blake, Jackson-Pratt, nasogastric, red rubber with holes) that can be attached to a suction source.

4. Placement of additional layer of reticulated sponge or gauze over suction tubing to separate suction from occlusive layer.

5. Placement of occlusive impermeable dressing, such as Ioban or Tegaderm, over the gauze/sponge and suction tubing.

6. Connect to suction source.

APPENDIX E: TETANUS IMMUNIZATION CHART

(Special Operations Forces Medical Handbook; US Department of Defense; Washington, DC: Government Printing Office)

Tetanus Immunization Status	Minor Clean Wound	Major Clean Wound	Contaminated Wound (War Wounds)
Fully immunized recent Td booster	N/A	N/A	N/A
Fully immunized Td booster 5–10 years ago	N/A	Tdap	Tdap
Fully immunized, no booster for >10 years	Tdap	Tdap	Tdap
Unknown, none, or incomplete immunization	Tdap	Tdap and TIG (250U)	Tdap and TIG (500U)

N/A, not applicable; Td, tetanus and diphtheria; Tdap, tetanus-diphtheria-acellular pertussis; TIG, tetanus immune globulin.

***Note**: Tetanus vaccination of mother gives her protection and protects the newborn in the first few weeks of life.*

Rabies Postexposure Immunization[21]		
Animal Type	**Evaluation & Disposition of Animal**	**Recommendations for Prophylaxis**
Dogs, cats, ferrets	Healthy and available for 10-day observation	Do not start unless animal develops symptoms, then immediately begin HRIG + vaccine
	Rabid or suspected rabid	Immediate HRIG + vaccine
	Unknown (escaped)	Consult public health officials
Skunks, raccoons, bats, foxes, coyotes, most carnivores	Regard as rabid	Immediate vaccination
Livestock, horses, rodents, rabbits; includes hares, squirrels, hamsters, guinea pigs, gerbils, chipmunks, rats, mice, woodchucks	Consider case-by-case	Consult public health officials. Bites of squirrels, hamsters, guinea pigs, gerbils, chipmunks, rats, mice, other small rodents, rabbits, and hares almost never require postexposure immunization.
If Not Previously Vaccinated		
Treatment	**Regimen**	
Local wound cleaning	All post-exposure treatment should begin with immediate, thorough	
Human rabies immune globulin (HRIG)	20 units per kg body weight given once on day 0. If anatomically feasible, the full dose should be infiltrated around the wound(s), or the rest should be administered IM in the gluteal area. If the calculated dose of HIRG is insufficient to inject all the wounds, it should be diluted with normal saline to allow infiltration around additional wound areas. HRIG should not be administered in the same syringe or into the same anatomical site as vaccine, or more than 7 days after the initiation of vaccine. Because HRIG may partially suppress active production of antibody, no more than the recommended dose should be given.	
Vaccine	Human diploid cell vaccine (HDCV), rabies vaccine adsorbed (RVA), or purified chick embryo cell vaccine (PCECV) 1 mL IM (deltoid area), one each days 0, 3, 7, 14.	
If Previously Vaccinated		
HRIG	Do not give	
Vaccine	HDCV or PCECV 1mL IM (deltoid area), one each on days 0 and 3.	

APPENDIX F: PACKING AND PLANNING CONSIDERATIONS

- This list is not all encompassing.
- Quantities of items listed are highly mission variable and up to provider discretion.
- All efforts were made to list items in common use.

Instruments	Hemorrhage control
• Metzenbaum scissors • Mayo scissors • Rat Tooth/Adson/DeBakey forceps • Kelly, Mosquito, Hemostat forceps • Allis forceps • Needle drivers • #10/#11/#15 scalpels • Volkmann or Weitlaner retractors • Bovie pen	• Combat Gauze/ChitoGauze • C-A-T[b] tourniquet/SOF Tactical tourniquet, wide[c]/Esmarch bandage/ sphygmomanometer with Esmarch bandage
Meds	**General supplies**
• Bacitracin/Silvadene • 2% Lidocaine with/without epinephrine • 8.4% sodium bicarbonate • 0.5% tetracaine hydrochloride (eye drops) • IV ertapenem • IV cefazolin • Oral moxifloxacin 400mg or oral levofloxacin 750mg • (Note: levofloxacin is preferred in wet/jungle environment) • Oral clindamycin 300mg • Pain and sedation medications • NaCl (for irrigation)/potable water source • Sterile water	• Alcohol pads • Betadine swabs • 1mL, 5mL, 10mL, 35mL, 60mL syringes • 19g Catheter • 18g IV 1.5", 25g 1.5" hard needle • Irrigation bulb • Basin • Chux pads • Gloves of various sizes (small, medium, large) • IV tubing • Large-bore catheter • Constricting band • Saline lock • Suture/ligature (see Appendix A) • Skin stapler • Cotton tip applicators • Morgan lens • Sterile drapes or draping material that can be sterilized • Surgical masks • Surgical gowns • Sterile gloves • Ioban 2–23" × 23" • Tegaderm • Suction tubing • Suction device (SSCOR Quickdraw suction; TAC-SET)
Dressings	
• Kerlix • 6", 4" Ace wrap • Coban[a] • 3", 2", 1" medical tape • Telfa/Adaptic • Silverlon • Dermabond/superglue • Steristrips	

[a]3M, http://www.3m.com;

[b]Combat Application Tourniquet, Composite Resources, http://combattourniquet.com/;

[c]Tactical Medical Solutions, https://www.tacmedsolutions.com.

APPENDIX G: WOUND MANAGEMENT SUMMARY TABLE

Goals of Wound Care	
• Hemorrhage control • Minimize risk of infection • Promote optimal healing • Reduce discomfort • Minimize disability/loss of function associated with treatment • Implement definitive care when possible	
Types of Wounds	
• Abrasion • Burn • Puncture • Laceration	• Gunshot • Blast • Crush injury
Telemedicine	
• Large or complex wounds • Associated injury to bone, blood vessel, tendon, nerve • Penetrating chest or abdominal wound • Infected wounds • Chronic, nonhealing wounds	
Irrigation	
Best	Irrigate wounds with dilute Dakin's solution or sterile isotonic solution.
Better	Irrigate wounds with clean potable tap water.
Minimum	Irrigate wounds with the cleanest water available (nonpotable water should be boiled for a minimum of 3 minutes and then cooled to body temperature).
Debridement	
Best	Use an assistant, remove nonviable tissue using sharp dissection (sterile scalpel or scissors) and control bleeding using tourniquet, topical hemostatic dressings, direct pressure, clamping, suture ligation, and/or electrocautery. Questionably viable tissue may be retained with repeat debridement once every 24–48 hours until arrival at surgical facility.
Better	Remove nonviable tissue using sharp dissection, control bleeding using tourniquet, topical hemostatic dressings, direct pressure, clamping, and/or suture ligation. Repeat debridement or delayed primary closure in 3–5 days.
Minimum	When unable to evacuate and resources for serial debridement every 24–48 hours are not available, remove all nonviable and questionably viable tissue using sharp dissection (clean blade or scissors) and control bleeding with tourniquet and/or direct pressure. Leave clean dressing in place then delayed primary closure in 4–7 days if no sign of infection (ICRC wound care method).
Dressings – Shallow wounds or abrasions	
Best	• Abrasions: Apply antibiotic ointment (e.g., Bacitracin or Silvadene) to skin, place nonadherent dressing over the area (e.g., Adaptic or Telfa), cover with absorbent gauze dressing, repeat daily. Alternative: Apply Silverlon dressing to a clean wound, cover with gauze, moisten gauze daily. Replace Silverlon every 3–5 days. • Puncture wounds or small open wounds: Apply absorbent gauze dressing, change when saturated with exudate or otherwise dirty, or at least once every 24 hours. • Small, clean lacerations: suture or Dermabond
Better	Apply any available sterile gauze dressing.
Minimum	Apply any available clean dressing.

Dressings – Deep or large open wounds	
Best	NPWT ・Commercial available kits such as the KCI Wound VAC device can be used to both cover the wound and promote wound healing. ・Field expedient wound VAC devices can be improvised from absorbent gauze, Tegaderm or Ioban, and suction tubing hooked up to a suction device. ・Change NPWT dressings every 2–3 days. ・Change NPWT dressings placed over infected wounds, along with wound debridement and irrigation, daily.
Better	Wet-to-dry dressing ・Wet-to-dry dressings using sterile isotonic fluid or clean water. ・Change the dressing 1–2 times per day unless the situation dictates a less frequent approach. ・For wounds that are draining heavily, a dry-to-wet dressing may be used instead.
Minimum	Place a bulky dressing with dry gauze, absorbent padding, and elastic bandage; leave in place 4–7 days if wound is clean without sign of infection.
Infection prevention	
・Tetanus prophylaxis if immunization status unknown ・In addition to wound care, treat open wounds with antibiotics as soon as possible after injury and continue for 24 hours with one of the following antibiotics: ・Moxifloxacin 400mg PO × 1 dose or levofloxacin 750mg PO × 1 dose ***Note:*** levofloxacin is preferred in wet/jungle environment ・Clindamycin 300mg PO every 8 hours ・Cefazolin 2g IV every 8 hours ・Ertapenem 1g IV 1 dose ・If following the ICRC wound care method, continue antibiotics for 5 days or until delayed primary closure.	
Infection treatment	
・Remove all dressings and inspect wound. ・Wounds that have been closed must be reopened. ・Repeat wound debridement to drain pus and remove all dead, infected tissue. If necessary, extend the wound with an incision in the long axis of the extremity. ・Worst-case scenario may require amputation of an extremity to control life-threatening infection. ・Increase the frequency of dressing changes to once or twice daily. ・Continue antibiotics for 7–10 days, moxifloxacin 400 mg PO daily or levofloxacin 750mg PO daily or ertapenam 1g IV daily, or alternative broad-spectrum antibiotic as available. ・Use Dakin's solution for the wet-to-dry dressing, particularly for suspected fungal and pseudomonal infections. ・Daily sugar or honey dressings for infected wounds may successfully treat infection in very austere settings	

NPWT, negative pressure wound therapy; VAC, vacuum-assisted closure.

APPENDIX H: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e., "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.
